*EUMeTrain Online Course , 10 – 30 June 2011*

**Christo Georgiev**  
*NIMH, Bulgaria*

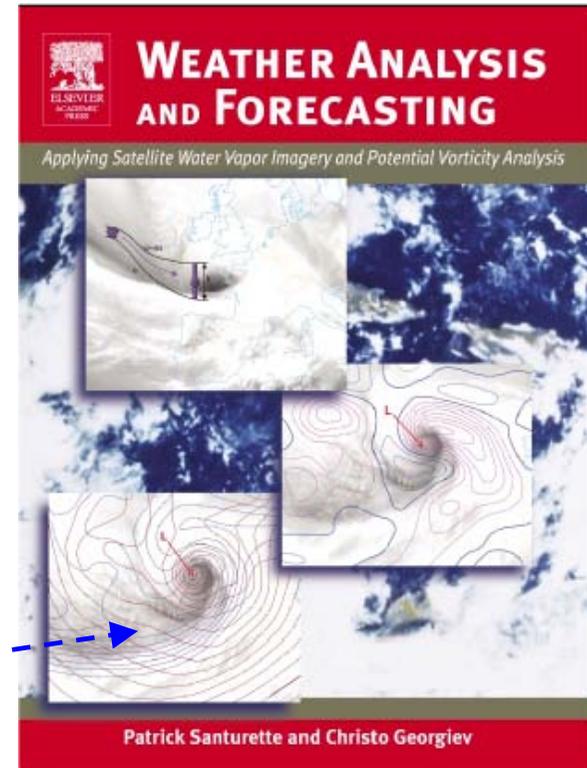

# INTRODUCTION

The radiometer SEVIRI of Meteosat Second Generation (MSG) provides data from 2 channels in the water vapour absorption band (6.2 and 7.3  $\mu\text{m}$ ).

Among these two WV channels, the radiation in Channel 6.2  $\mu\text{m}$  is more easily absorbed by water vapour and has a larger information content.

Channel 6.2  $\mu\text{m}$  is the primary WV channel, broadly used in image format for the purposes of weather analysis and forecasting based on its synoptic scale interpretation , see e.g.

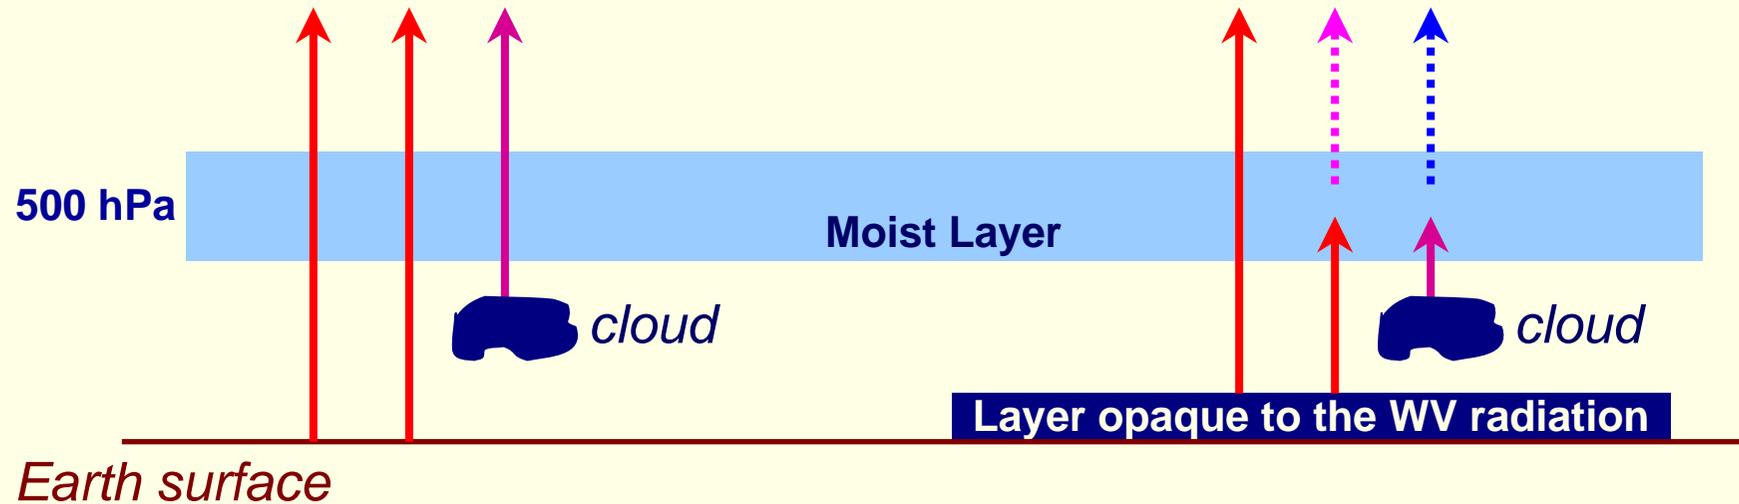

Weldon & Holmes (1991); Bader et al., 1995; Santurette & Georgiev, 2005.

The other MSG WV channel 7.3  $\mu\text{m}$  can also be used in operational forecasting environment for detecting mid-level moisture features associated with low-level thermodynamic conditions.

# Radiance

The satellite measures intensity of radiation that is referred to as 'radiance', and may be converted to brightness temperature, or to image grey shade. The radiance in window IR and WV channels is emitted by objects such as cloud top elements and the earth surface.

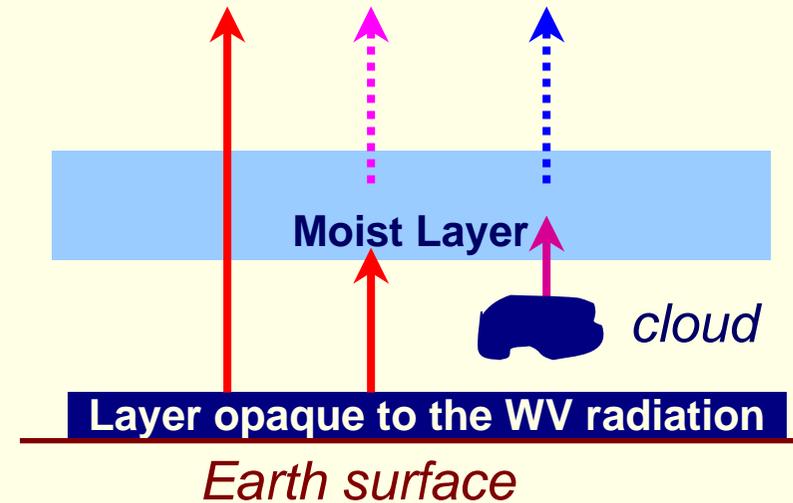

- The radiation in **IR window** channels (10.8  $\mu\text{m}$ ) will reach the satellite after no absorption. The derived brightness temperature equals the physical temperature of the object, which radiates.

- For the **WV channels** (6.2  $\mu\text{m}$ ), some portion of the upcoming radiation is absorbed by water vapour and then re-emitted by the atmosphere.

The absorption and re-emission depends on the vapour pressure in various ways for different channels.

Two **radiation effects** are of special importance for interpretation and application of data from the WV absorption channels (see Georgiev et al. 2007):

- ✓ The **effect of portioning** between the contributions of the radiation originating from below, which penetrates through the moist layer and the radiation emitted by the moist layer itself.

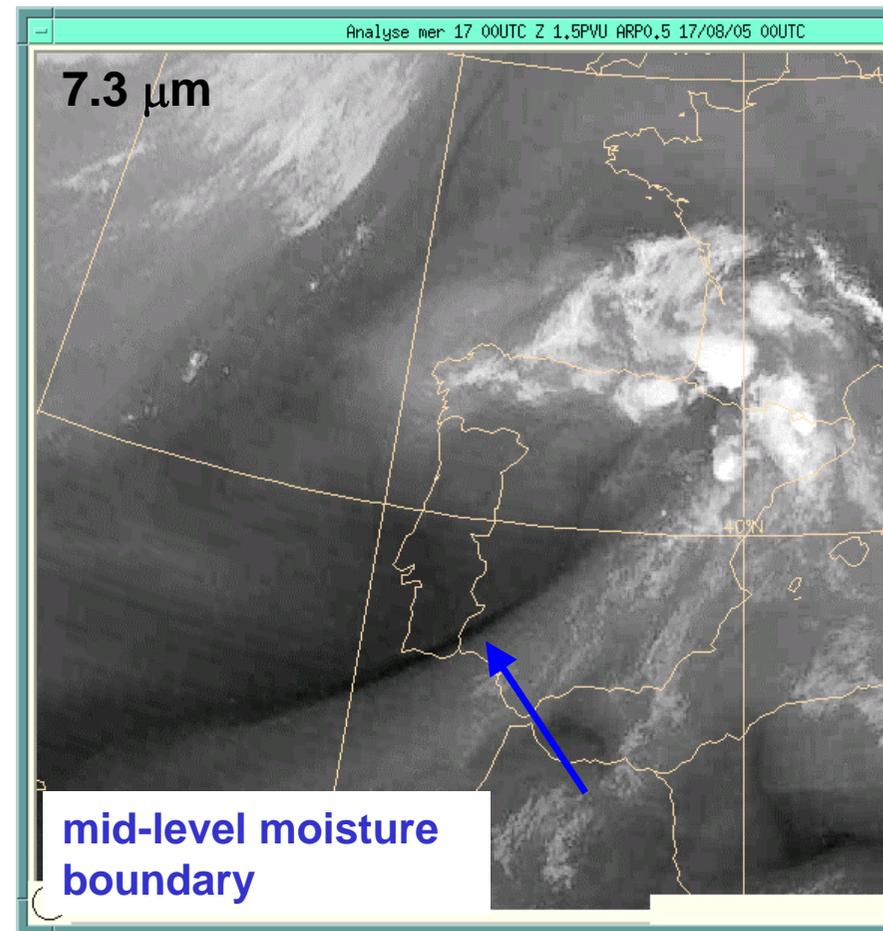

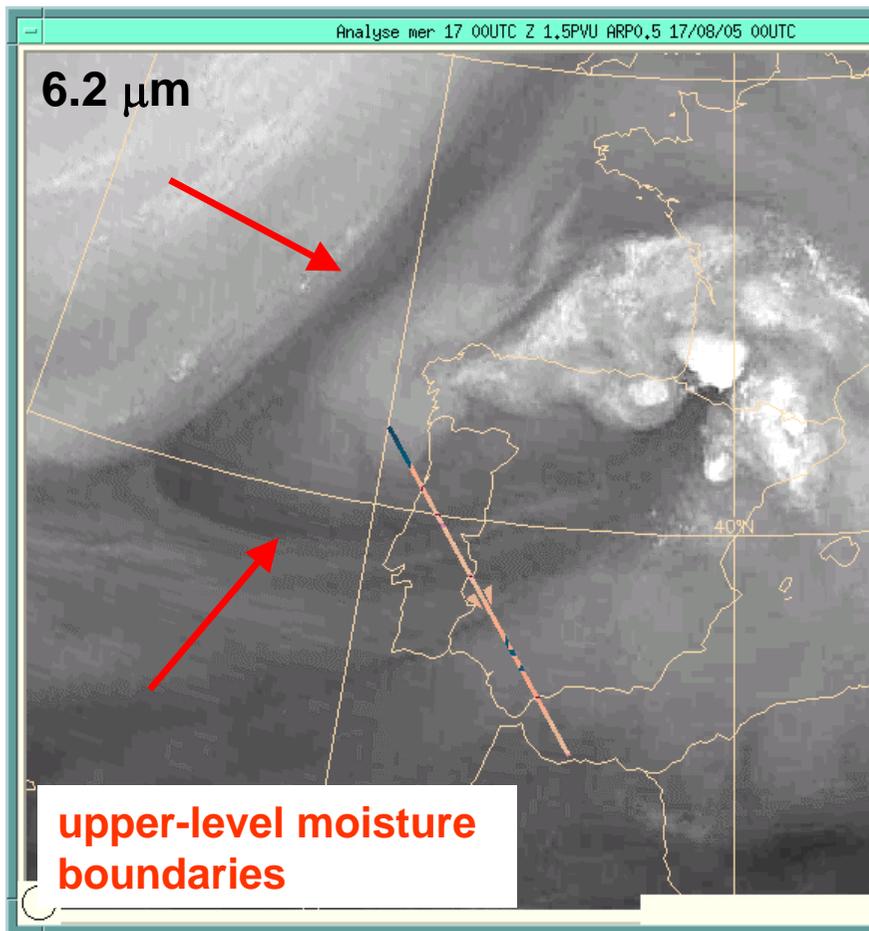

The “portioning effect” influences the radiation of 6.2  $\mu\text{m}$  and 7.3  $\mu\text{m}$  channels in different ways and allows these channels to be sensitive to tropospheric moisture at different altitudes.

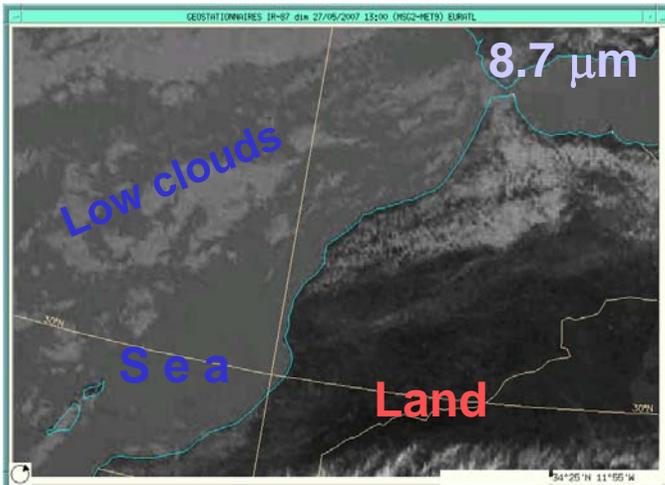

- ✓ The “**sensitivity range**”, which provides an indication of the channels’ ability to detect differences in humidity of atmospheric layers at various altitudes.

(for details see end of the presentation)

## WV IMAGES in CHANNELS 6.2 and 7.3 $\mu\text{m}$

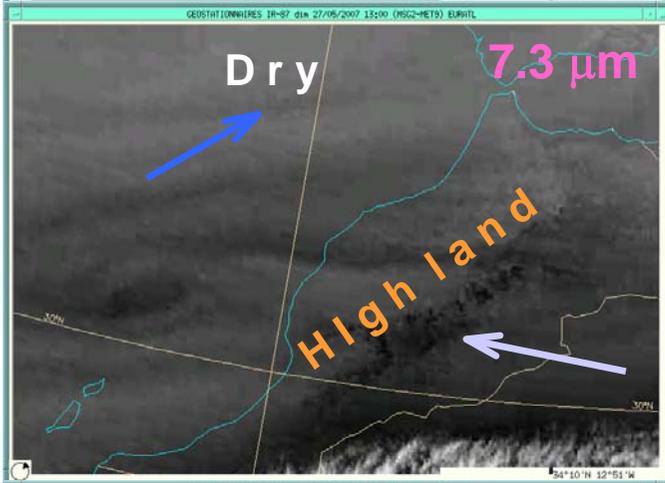

The imagery features in the two MSG WV channels may differ significantly in situations of strong troposphere dynamics. The radiance in WV 6.2 channel depends on the temperature and humidity only above 600 hPa and only upper-level structures are visible by the 6.2  $\mu\text{m}$ , the lower humidity being displayed in darker grey shades. The 7.3  $\mu\text{m}$  radiance is sensitive to moisture patterns in middle troposphere and some low-level features can be visible by this channel in certain conditions.

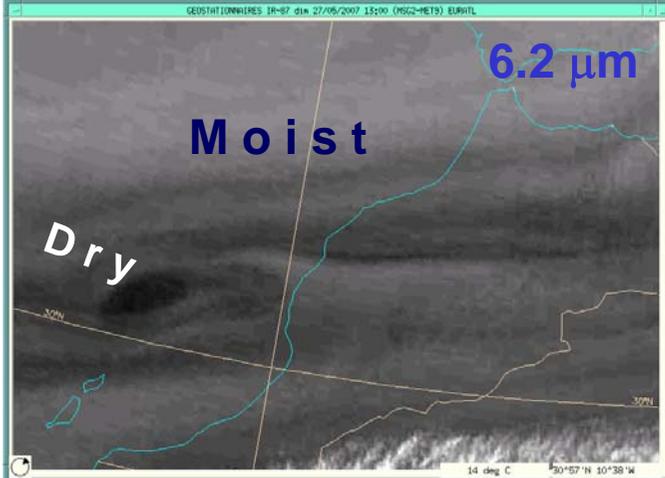

## 8.7 $\mu\text{m}$ IR channel:

- Radiation reaching the satellite is slightly absorbed by atmospheric water vapour.
- Various objects of the earth surface and atmosphere may be distinguished due to differences in their temperature.

## 7.3 $\mu\text{m}$ WV channel:

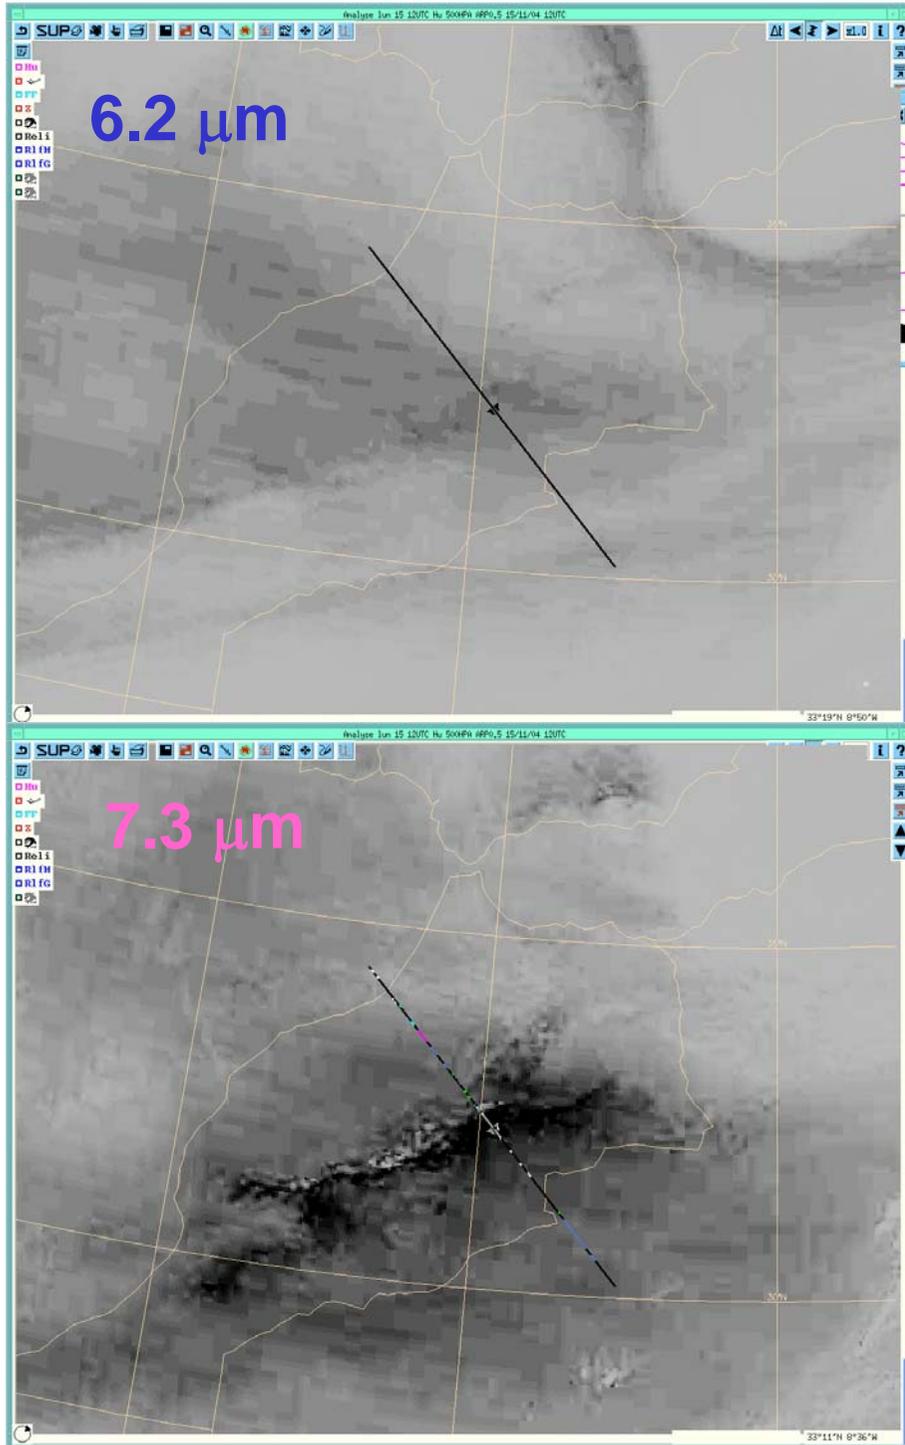

- Radiation is sensitive to detect mid- to low-level atmospheric moisture and mid/high-level clouds.
- Low-level clouds may be not visible in case of moist air above these clouds.
- High mountain surface may be seen as a dark feature if little moisture is present above.

## 6.2 $\mu\text{m}$ WV channel:

- Radiation is sensitive to upper- and mid-level atmospheric moisture. Due to strong absorption, low-level features (earth surface, low clouds) are not visible.

# Upper-level moisture

Looking at the image grey shades in the 6.2  $\mu\text{m}$  and 7.3  $\mu\text{m}$  MSG channels, indicate the position of the following vertical moisture distribution:

- Dry air stripe at upper troposphere
- and
- Moist mid-level air below.

# **WV imagery 6.2 $\mu\text{m}$**

## **Synoptic applications**

- **The water vapour is a conservative tracer of upper-level large scale atmospheric motion (which, in its great part, is approximately adiabatic and hydrostatic).**
- **Therefore WV images provide general information on the flow patterns at mid-upper troposphere (600 – 300 hPa).**
- **The basis for synoptic scale applications of WV imagery is that moist and dry regions as well as the boundaries between them often relate to significant upper-level flow features such as troughs and ridges, deformation zones, jet streams, vorticity, blocking regime.**
- **A relevant dynamic approach is needed for an efficient operational use of WV images in order to link the satellite information to the dynamics of upper-troposphere.**

## **6.2 $\mu\text{m}$ WV IMAGERY DIAGNOSIS**

### **UPPER-LEVEL**

*Potential Vorticity Analysis  
by using WV imagery*

# Potential Vorticity Concept

- The Potential Vorticity (PV) is a product of the absolute vorticity and the static stability (Hoskins, B., 1997).

**Units:**  $10^{-6} \text{ m}^2 \text{ s}^{-1} \text{ K kg}^{-1}$  or 'PV-unit' (PVU)

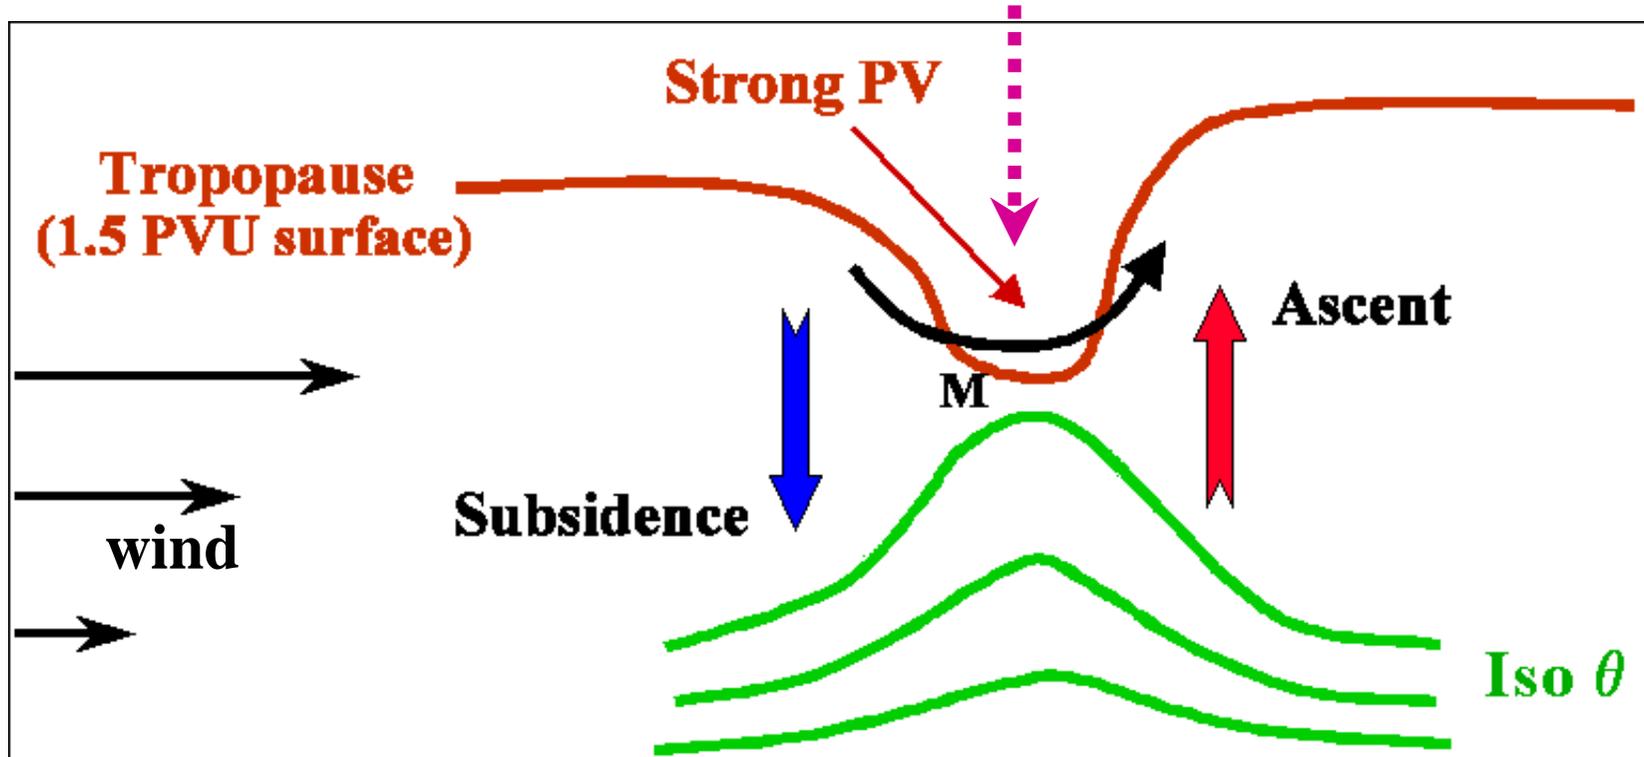

- The PV is an effective parameter for studying the appearance and evolution of dynamical structures at synoptic scale due to its important properties (see Santurette & Georgiev, 2005) :

- ✓ **Conservation for adiabatic frictionless motions**

- ✓ **Specific climate distribution in the atmosphere**

- In the middle and upper troposphere PV is ranging from 0.5 to 1.0 PVU
- In the stratosphere  $\text{PV} > 3.0 \text{ PVU}$  due to the strong increase of the static stability.

## TROPOPAUSE DYNAMIC ANOMALY

In terms of the PV concept, the tropopause in mid-latitudes may be represented by the surface of constant PV = 1.5 PVU ( $10^{-6} \text{ m}^2 \text{ s}^{-1} \text{ K kg}^{-1}$ ), and considered as the “dynamical tropopause” (see Santurette & Georgiev, 2005).

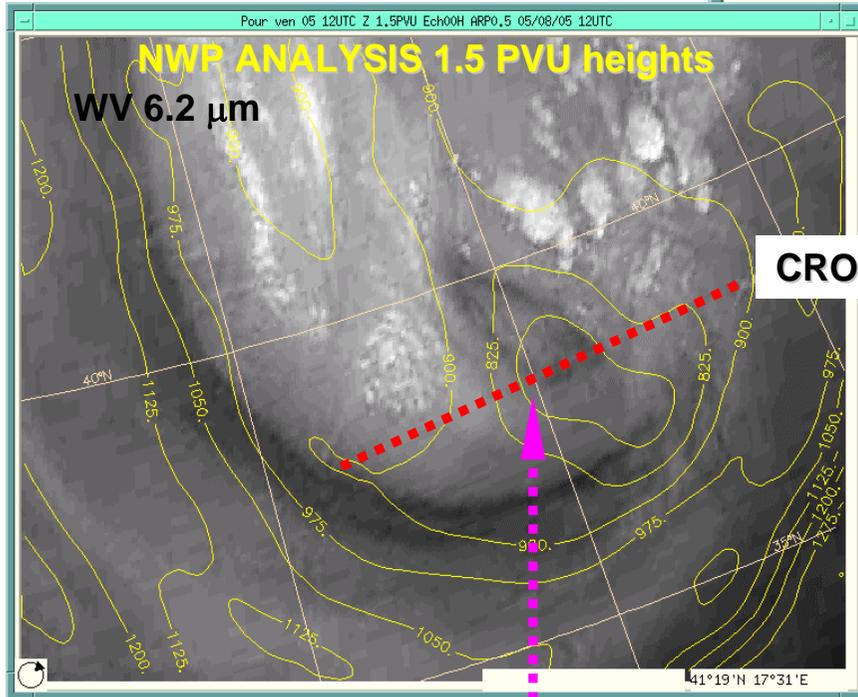

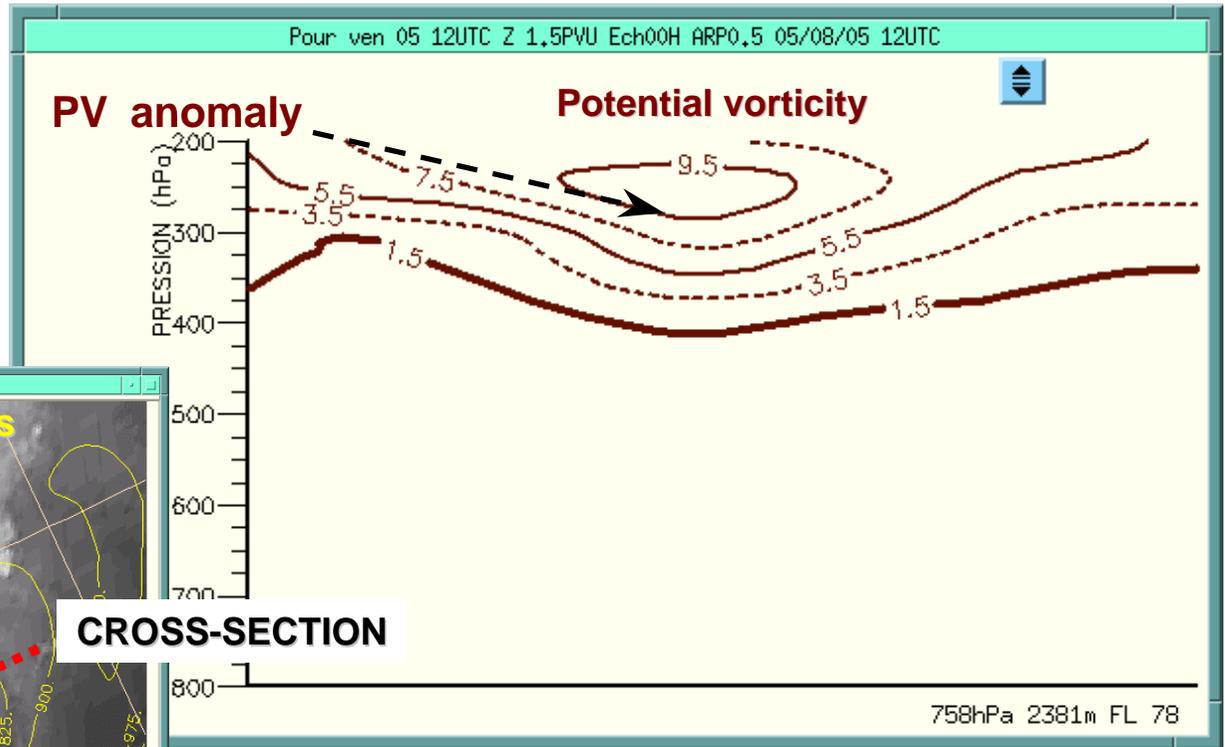

An upper tropospheric anomaly of high PV, advected down to middle troposphere corresponds to an area of the folding of the dynamical tropopause associated with a stratospheric intrusion.

Such a low tropopause area is referred to as a PV anomaly or a “tropopause dynamic anomaly”.

In the upper-air analysis, the most significant dynamic feature is the PV anomaly (or tropopause dynamic anomaly)

CROSS-SECTION

05/08/2005 1200 UTC

CROSS-SECTION

How the PV anomaly influences the troposphere thermodynamics in the real atmosphere, analyzed by a NWP model?

PV anomaly (or tropopause dynamic anomaly) is seen in a 6.2  $\mu\text{m}$  image as a dark dry zone or vorticity feature

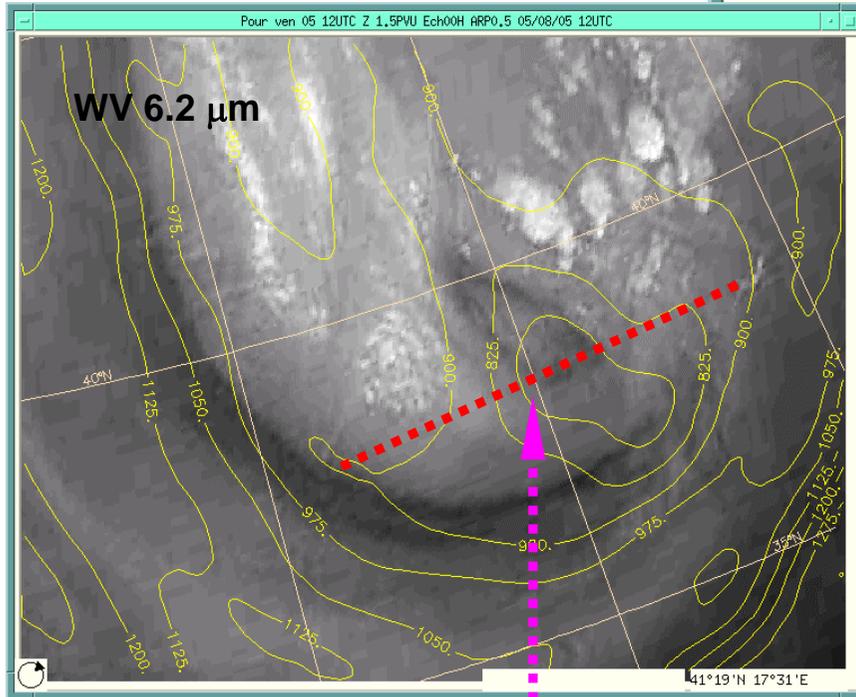

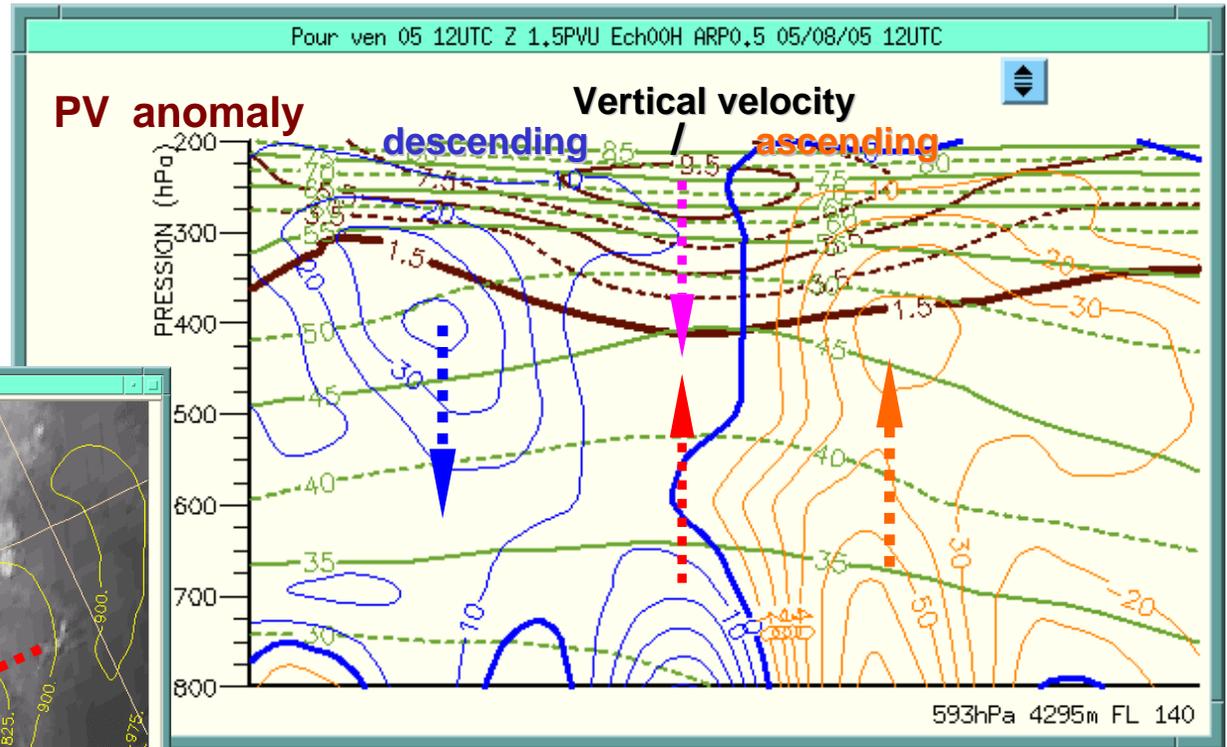

In the upper-air analysis, the most significant dynamic feature is the **PV anomaly** (or tropopause dynamic anomaly)

CROSS-SECTION

05/08/2005 1200 UTC

NWP ANALYSIS 1.5 PVU heights

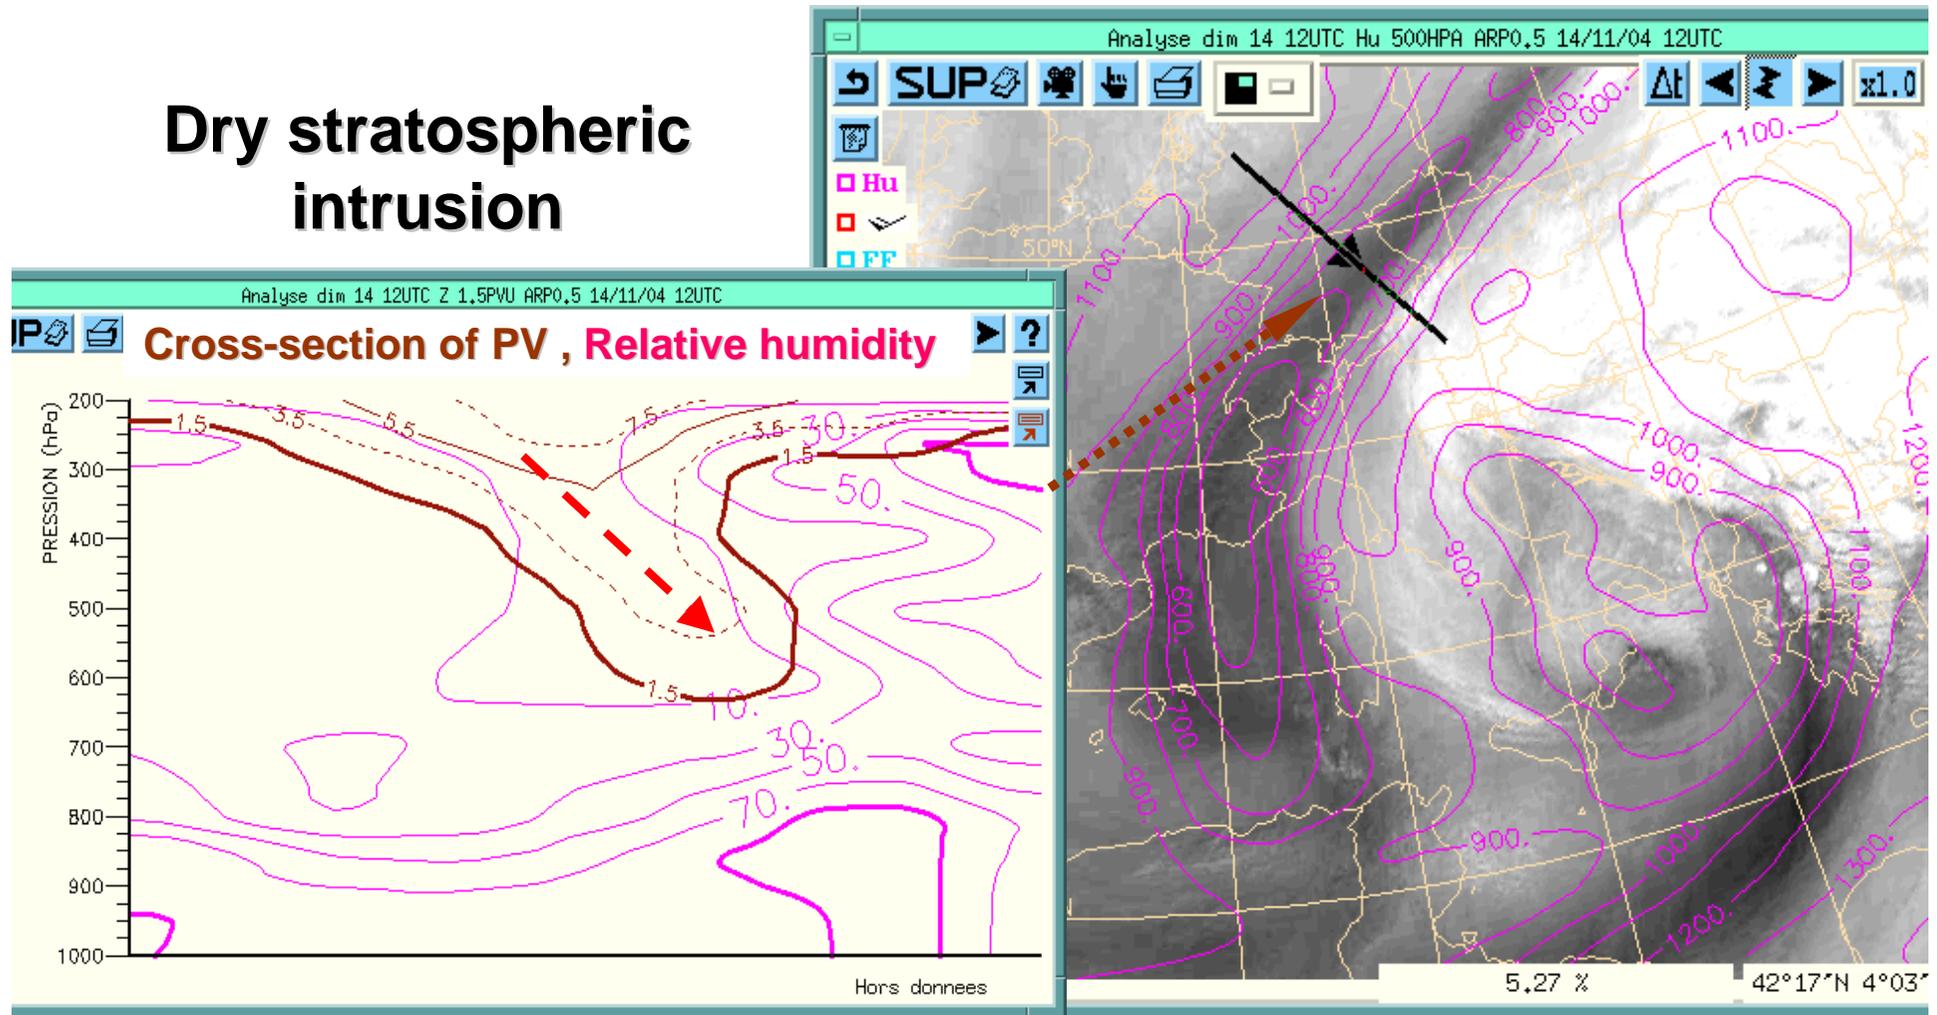

**PV anomaly** (or tropopause dynamic anomaly) seen in a 6.2  $\mu\text{m}$  image as a dark dry zone or vorticity feature

In a baroclinic flow increasing with height, the intrusion of PV anomaly in the troposphere produces vertical motion: the **deformation of the potential temperature surfaces induces**

**ascending motion ahead of the anomaly**  
&  
**descending motion behind the anomaly**

# Tropopause dynamic anomaly

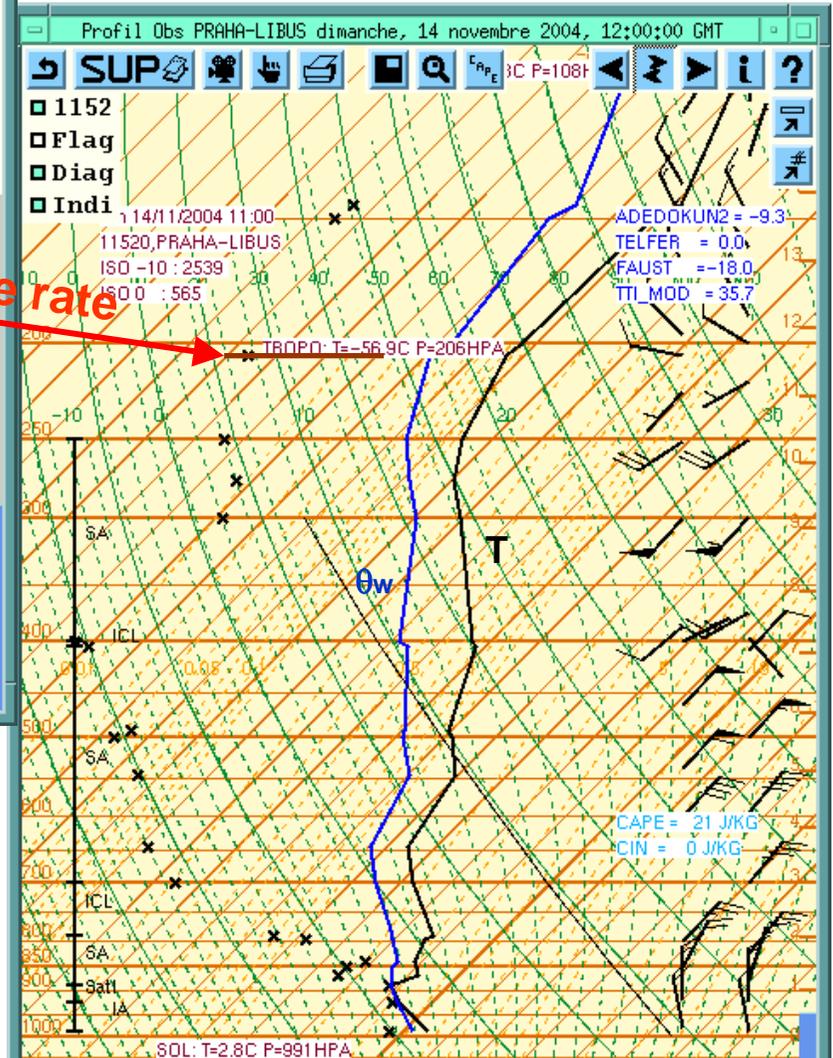

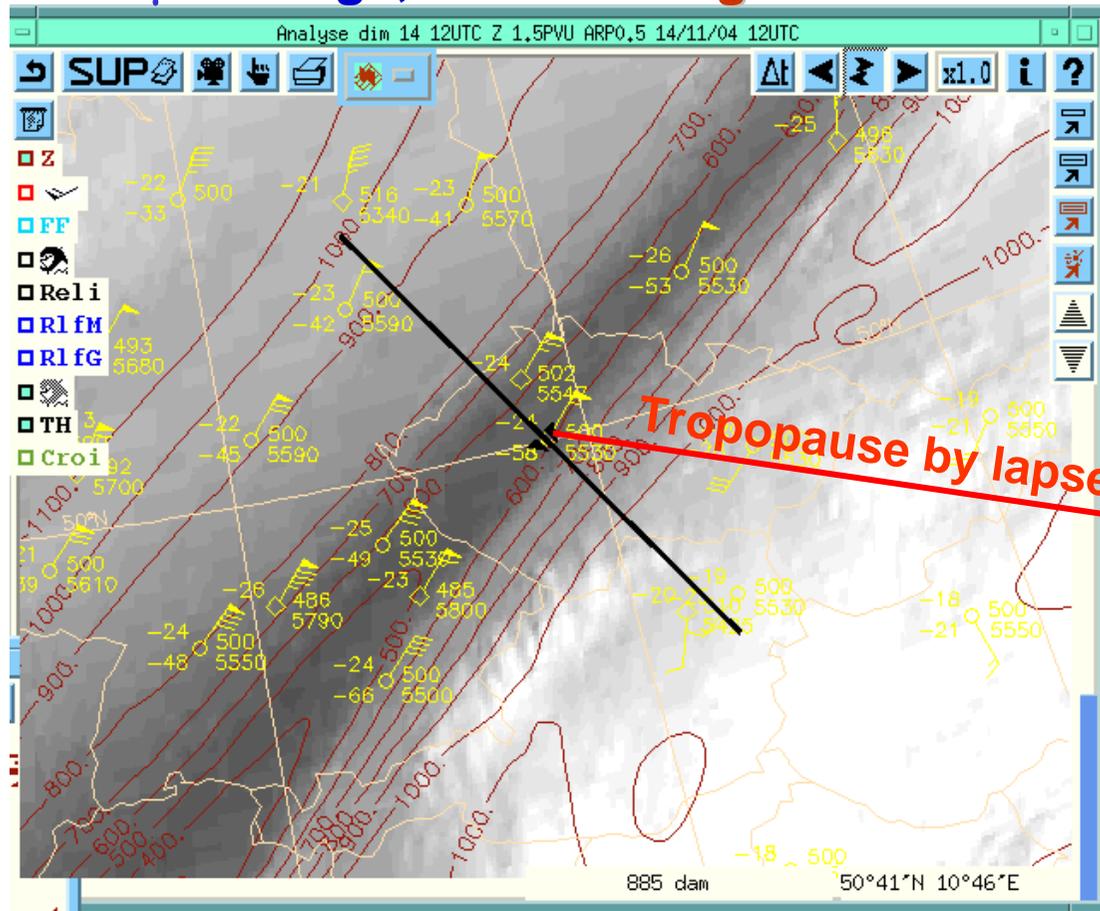

## Dry stratospheric intrusion

A PV anomaly is associated with very dry stratospheric air down to middle troposphere along with the zone of tropopause folding. The NWP model sees the dynamical tropopause at 600 hPa confirmed by the WV image.

# PV concept and upper air soundings

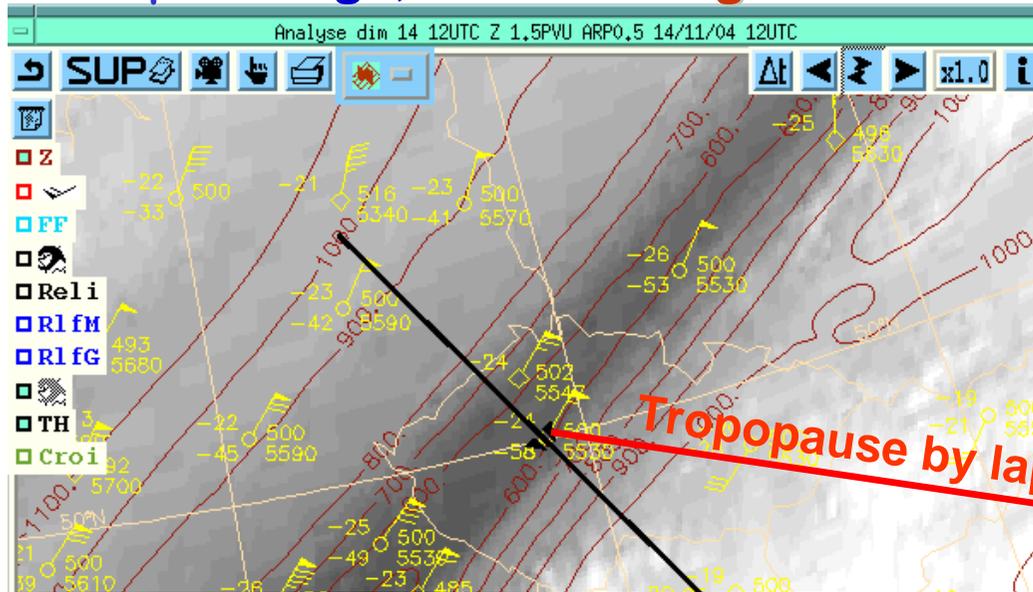

## 6.2 $\mu\text{m}$ image, 1.5 PVU heights

The tropopause level, derived by using temperature lapse rate is not correct with references to the wind field and WV image (as an observational tool) in terms of PV concept.

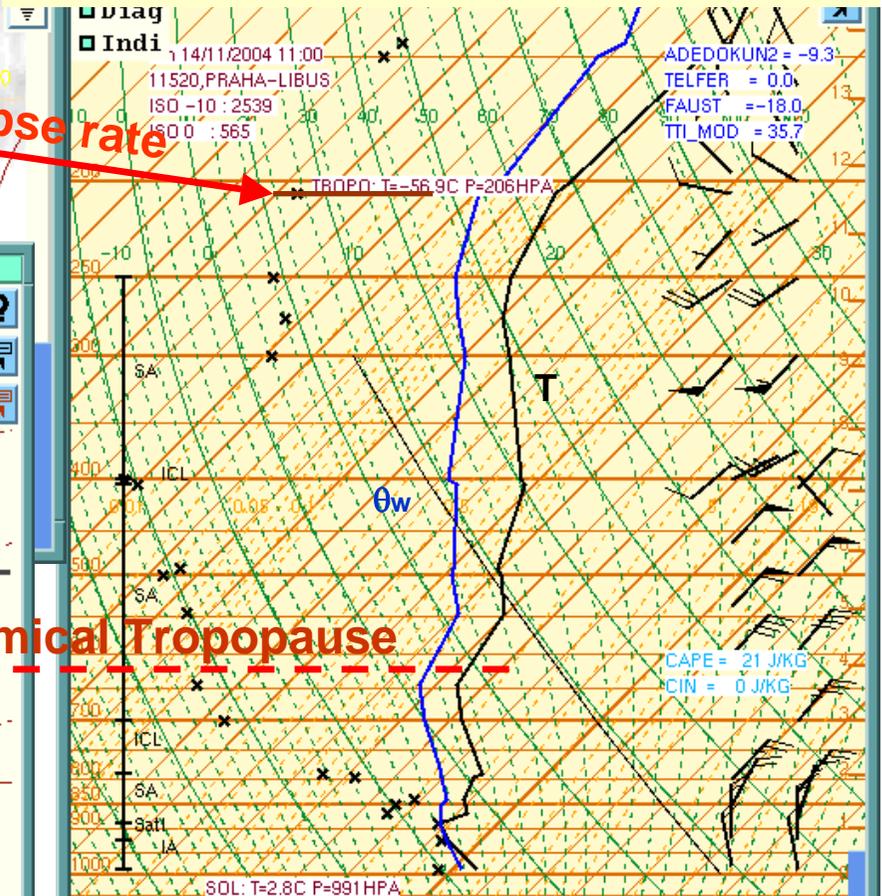

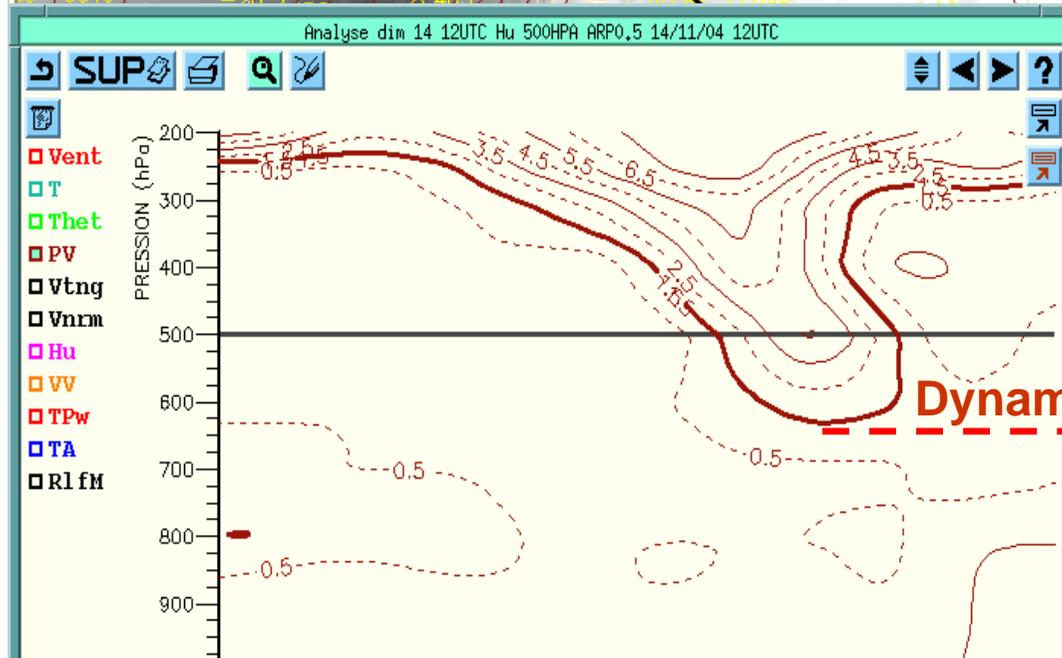

# PV concept and upper air soundings

## 6.2 $\mu\text{m}$ image, 1.5 PVU heights

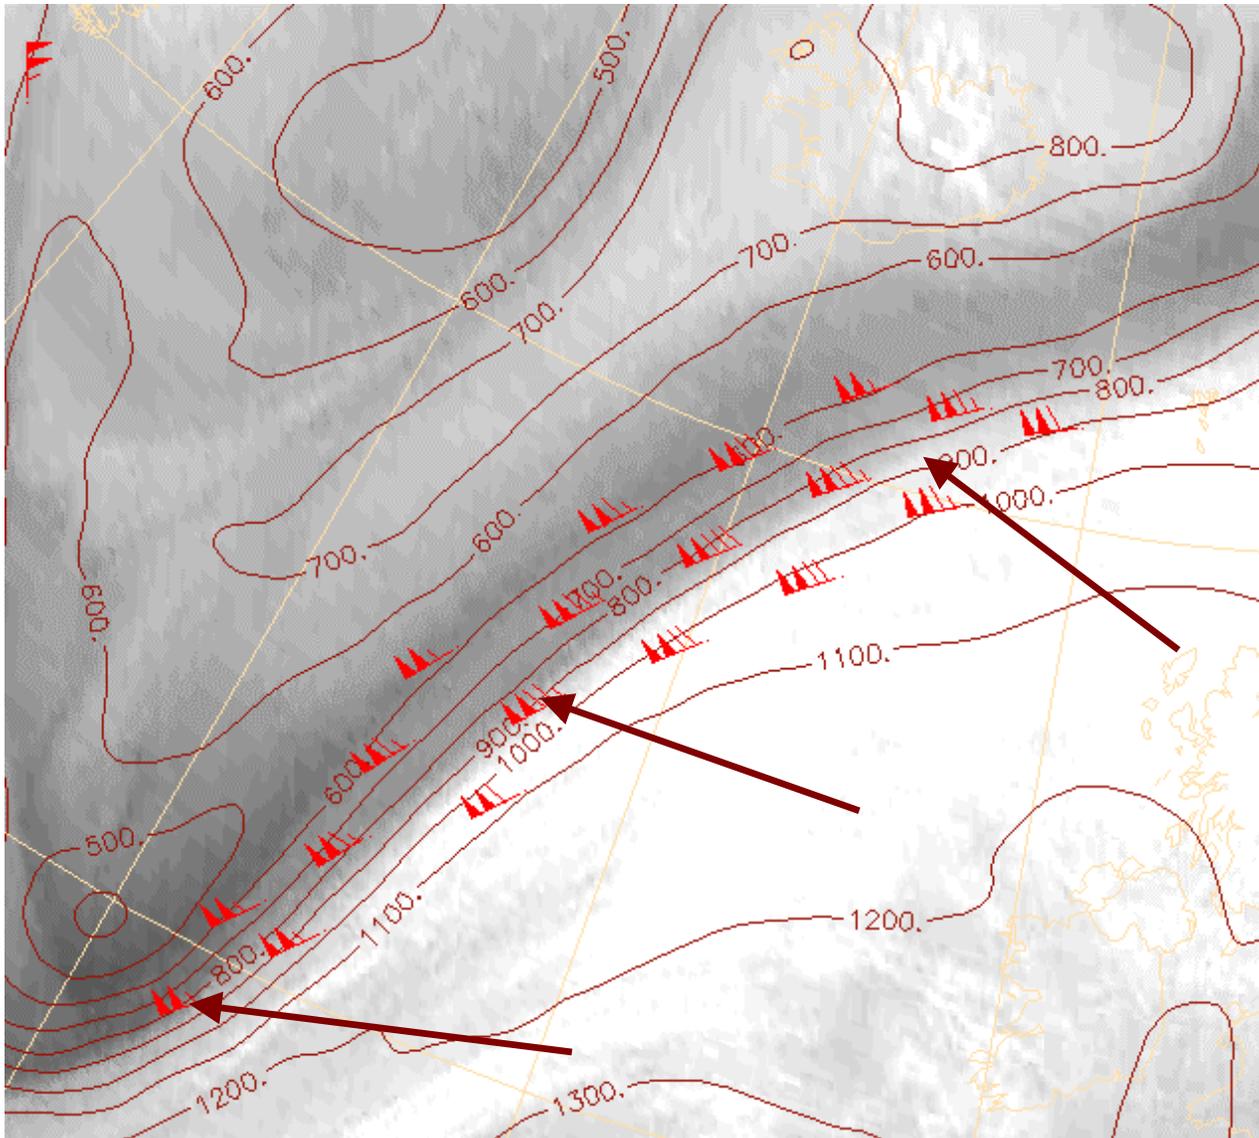

Above the sounding release point:

- High gradient of 1.5 PVU surface heights
- WV image dark zone
- Dynamical tropopause at 600 hPa analysed by the NWP model.

# WV imagery and mid/upper level dynamical fields

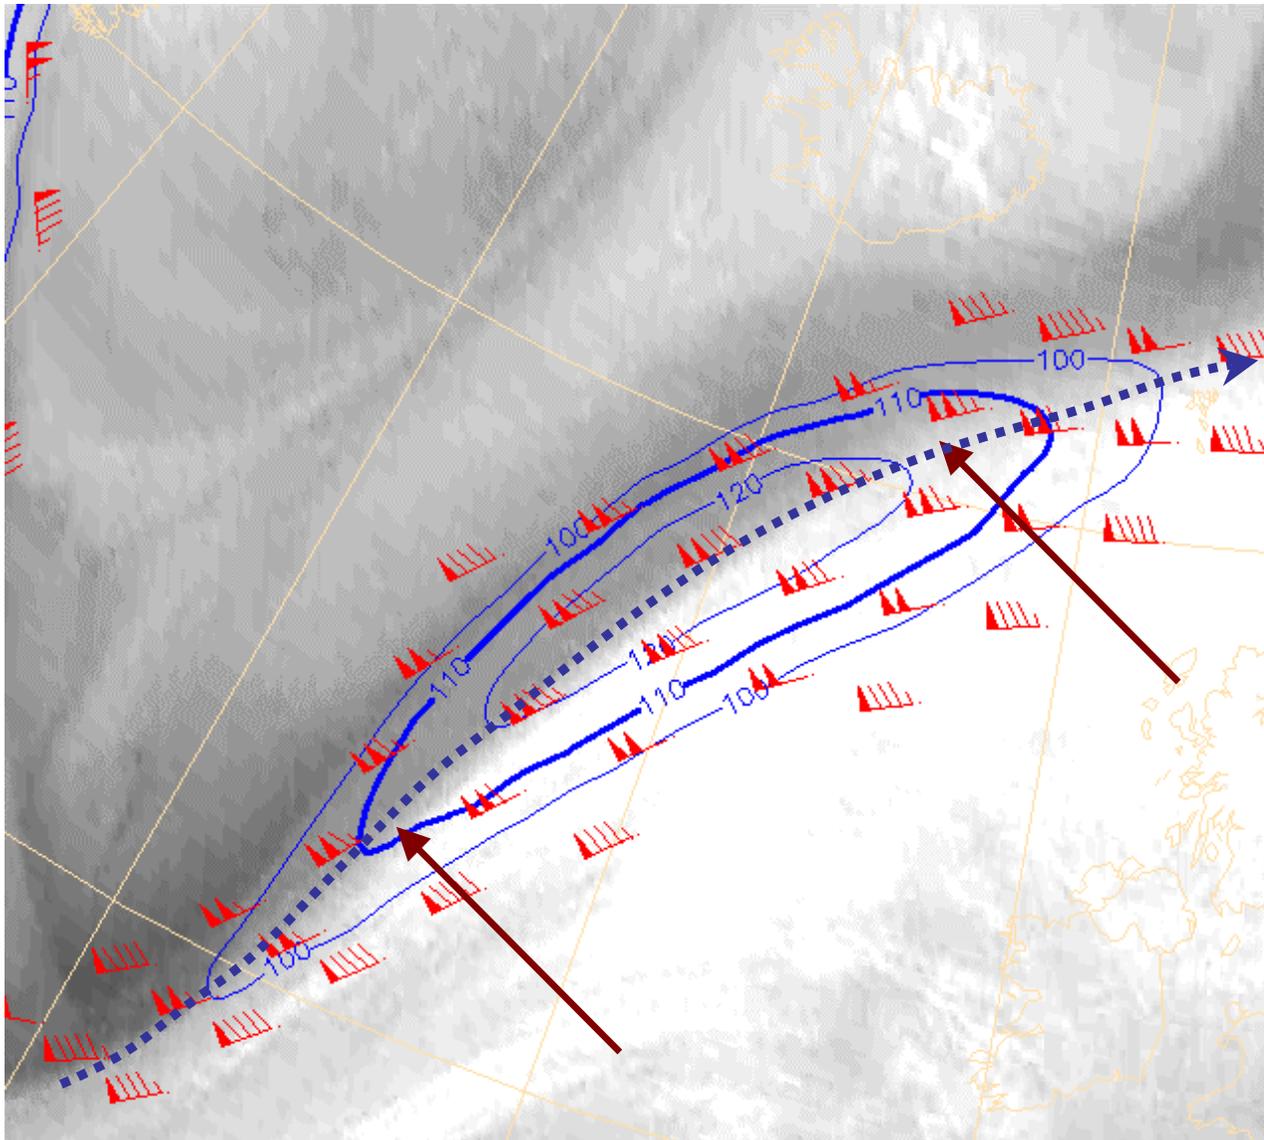

1.5 PVU surface heights / wind at 300 hPa (only > 100 kt)

An area of strong gradient of the dynamical tropopause heights produces sharp boundary between different moisture regime on the WV image:  
Stratospheric (dry) and Tropospheric (moist) air. This boundary is also aligned with the zone of the highest upper-level wind speed.

# WV imagery and mid/upper level dynamical fields

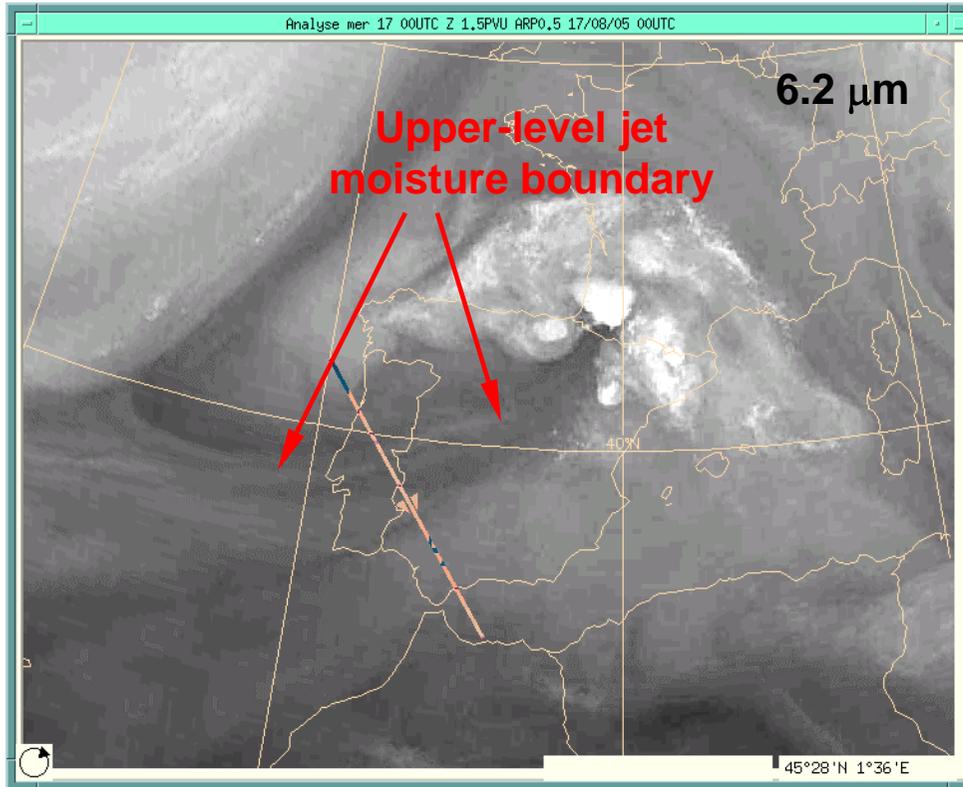

Contours of wind speed > 100 kt / wind > 80 kt at 300 hPa

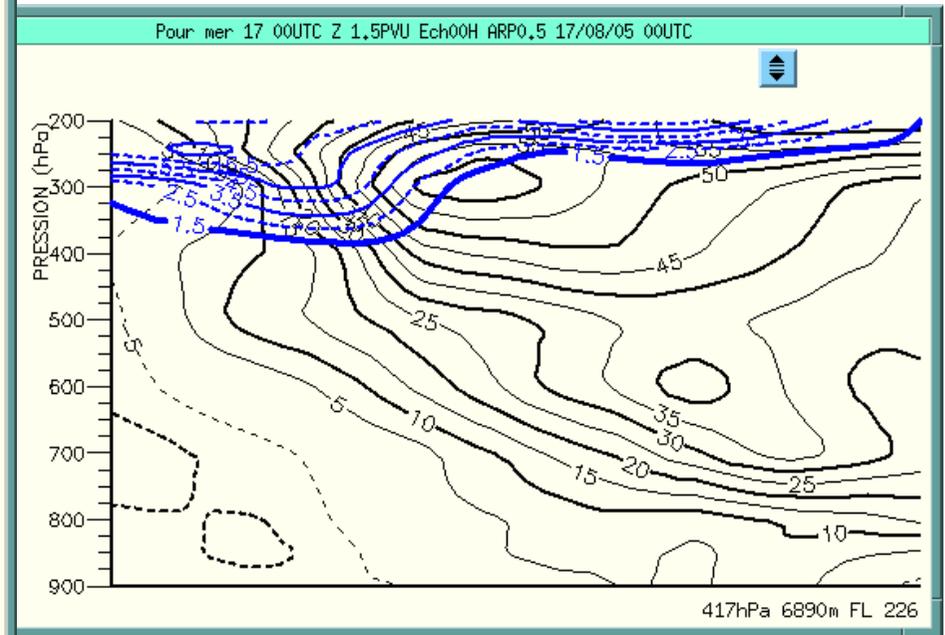

Generally, the moisture boundaries on the WV images oriented from southwest to northeast are nearly coincident with well defined jet stream axes.

The jet streak is likely along the most contrast part of the moisture boundary in the WV image.

# UPPER-LEVEL JET AND PV ANOMALY

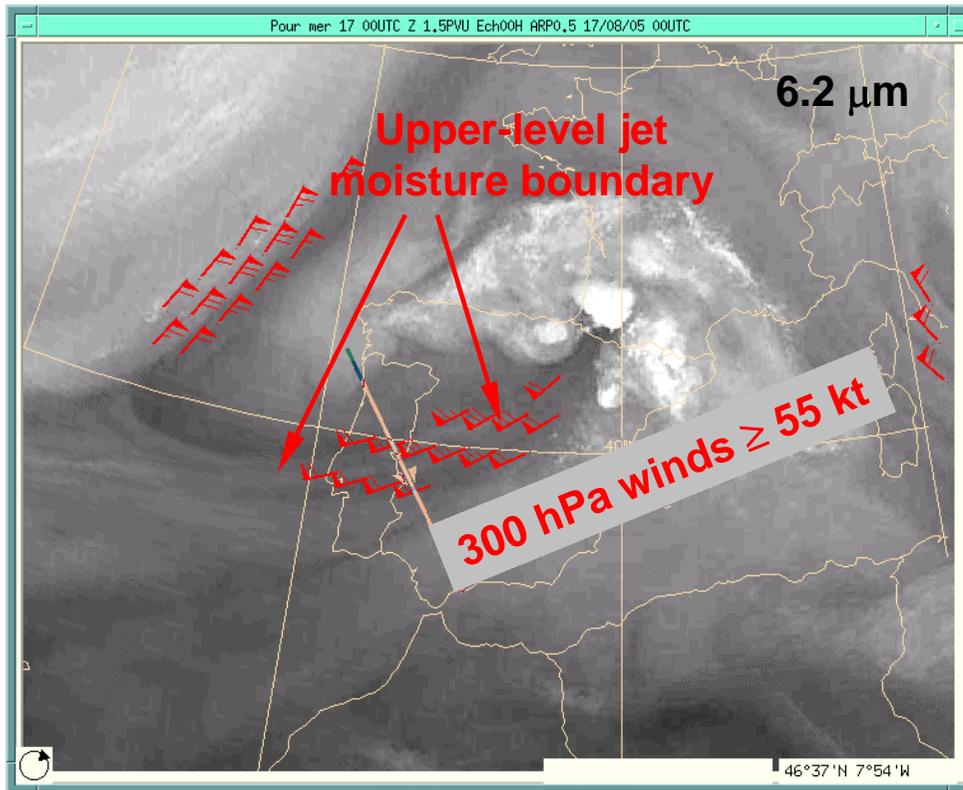

## Cross-section of wind and potential vorticity (PV)

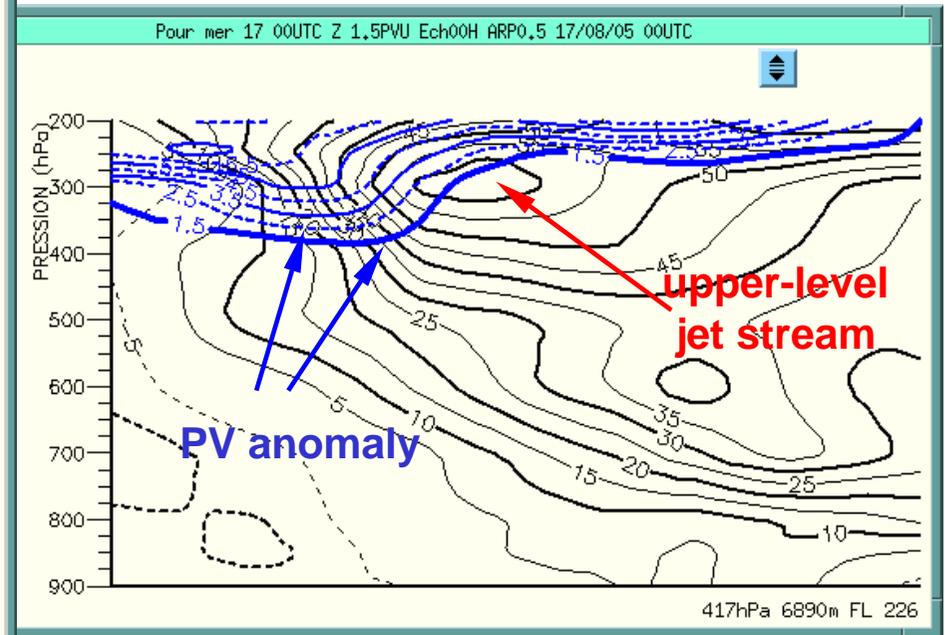

The dynamical structure of the jet stream zone in the view of the PV concept may be seen in the vertical cross-section across the moisture boundary in the 6.2  $\mu\text{m}$  image.

# UPPER-LEVEL JET AND PV ANOMALY

## Cross-section of wind and potential vorticity (PV)

The dynamical structure of the jet stream zone in the view of the PV concept: vertical cross-section across the moisture boundary in the 6.2  $\mu\text{m}$  image.

The position of the maximum wind-speed contour coincides with the zone of folding of the tropopause (1.5 PVU constant surface) associated with an upper-troposphere PV anomaly.

## **6.2 $\mu\text{m}$ WV IMAGERY DIAGNOSIS**

### **UPPER-LEVEL FORCING OF CYCLOGENESIS**

**A case over the Eastern Mediterranean  
18 – 20 March 2009**

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$  image

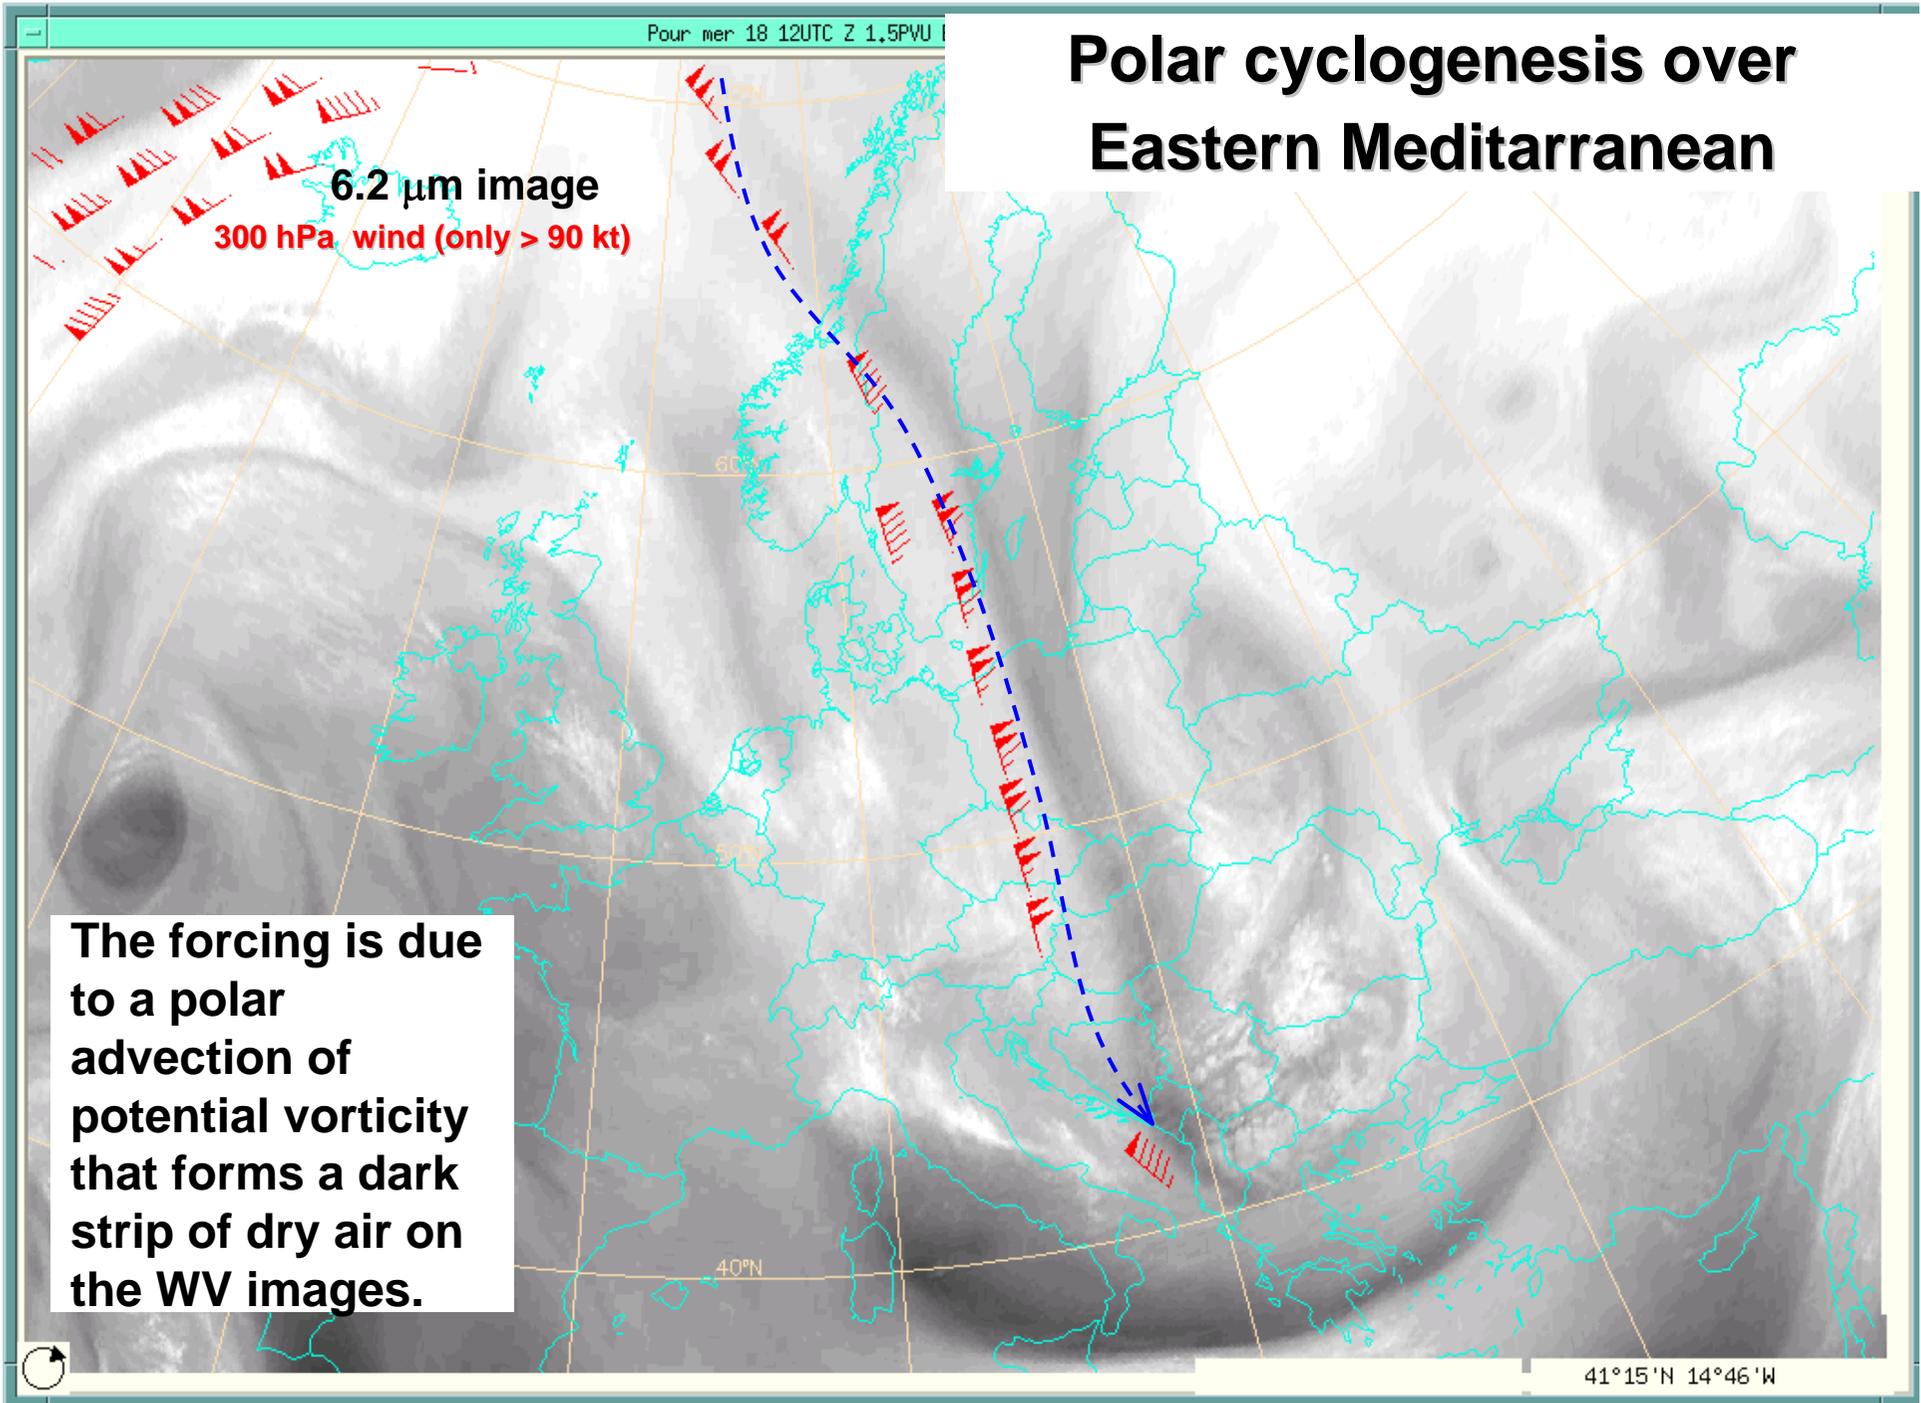

300 hPa wind (only > 90 kt)

1.5 PVU height (only < 1000 dam)

Upper-level forcing of cyclogenesis occurs in the Mediterranean with penetration of high PV deeply south along with a strong northerly jet.

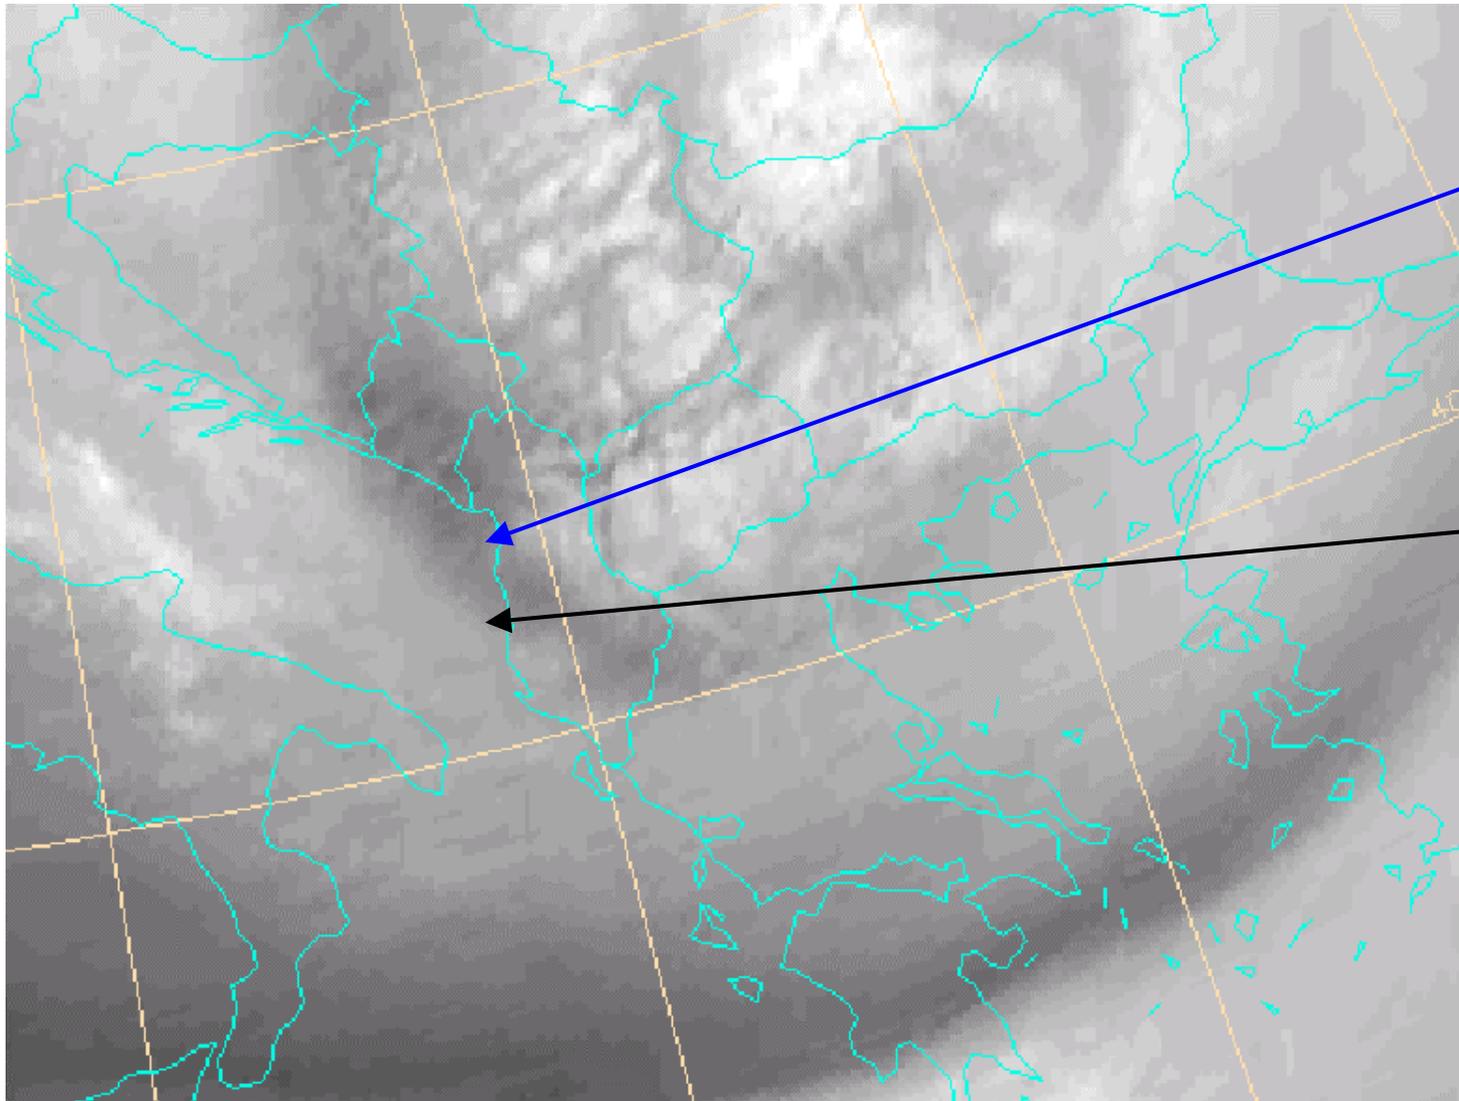

# Polar cyclogenesis over Eastern Mediterranean

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$ , 1.5 PVU height (> 1000 dam), 300 hPa wind (> 90 kt), 850 hPa  $\theta_w$  (> 6  $^{\circ}\text{C}$ ) 12 UTC

## Ingredients:

### Tropopause anomaly:

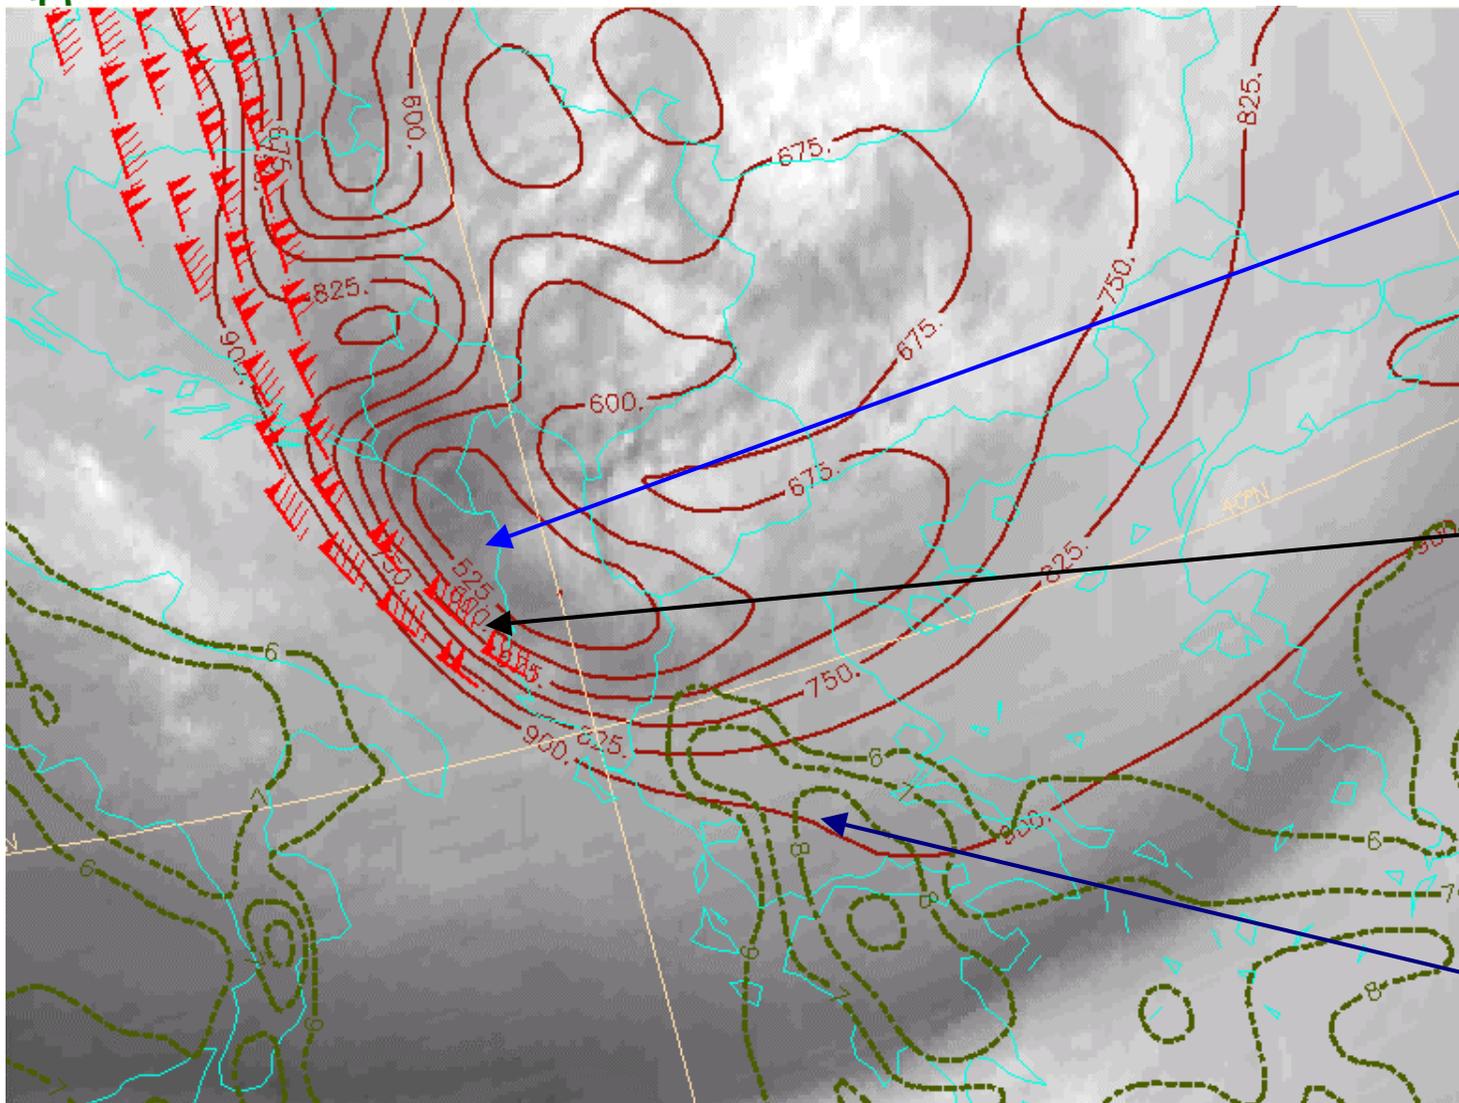

- WV image dark zone

### Polar jet stream

- WV image moisture boundary

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$ , 1.5 PVU height < 900 dam), and 1.5 PVU wind (> 90 kt), 850 hPa  $\theta_w$  (> 6) 12 UTC

## Ingredients:

### Tropopause anomaly:

- WV image dark zone
- low (500hPa) dynamical tropopause

### Polar jet stream

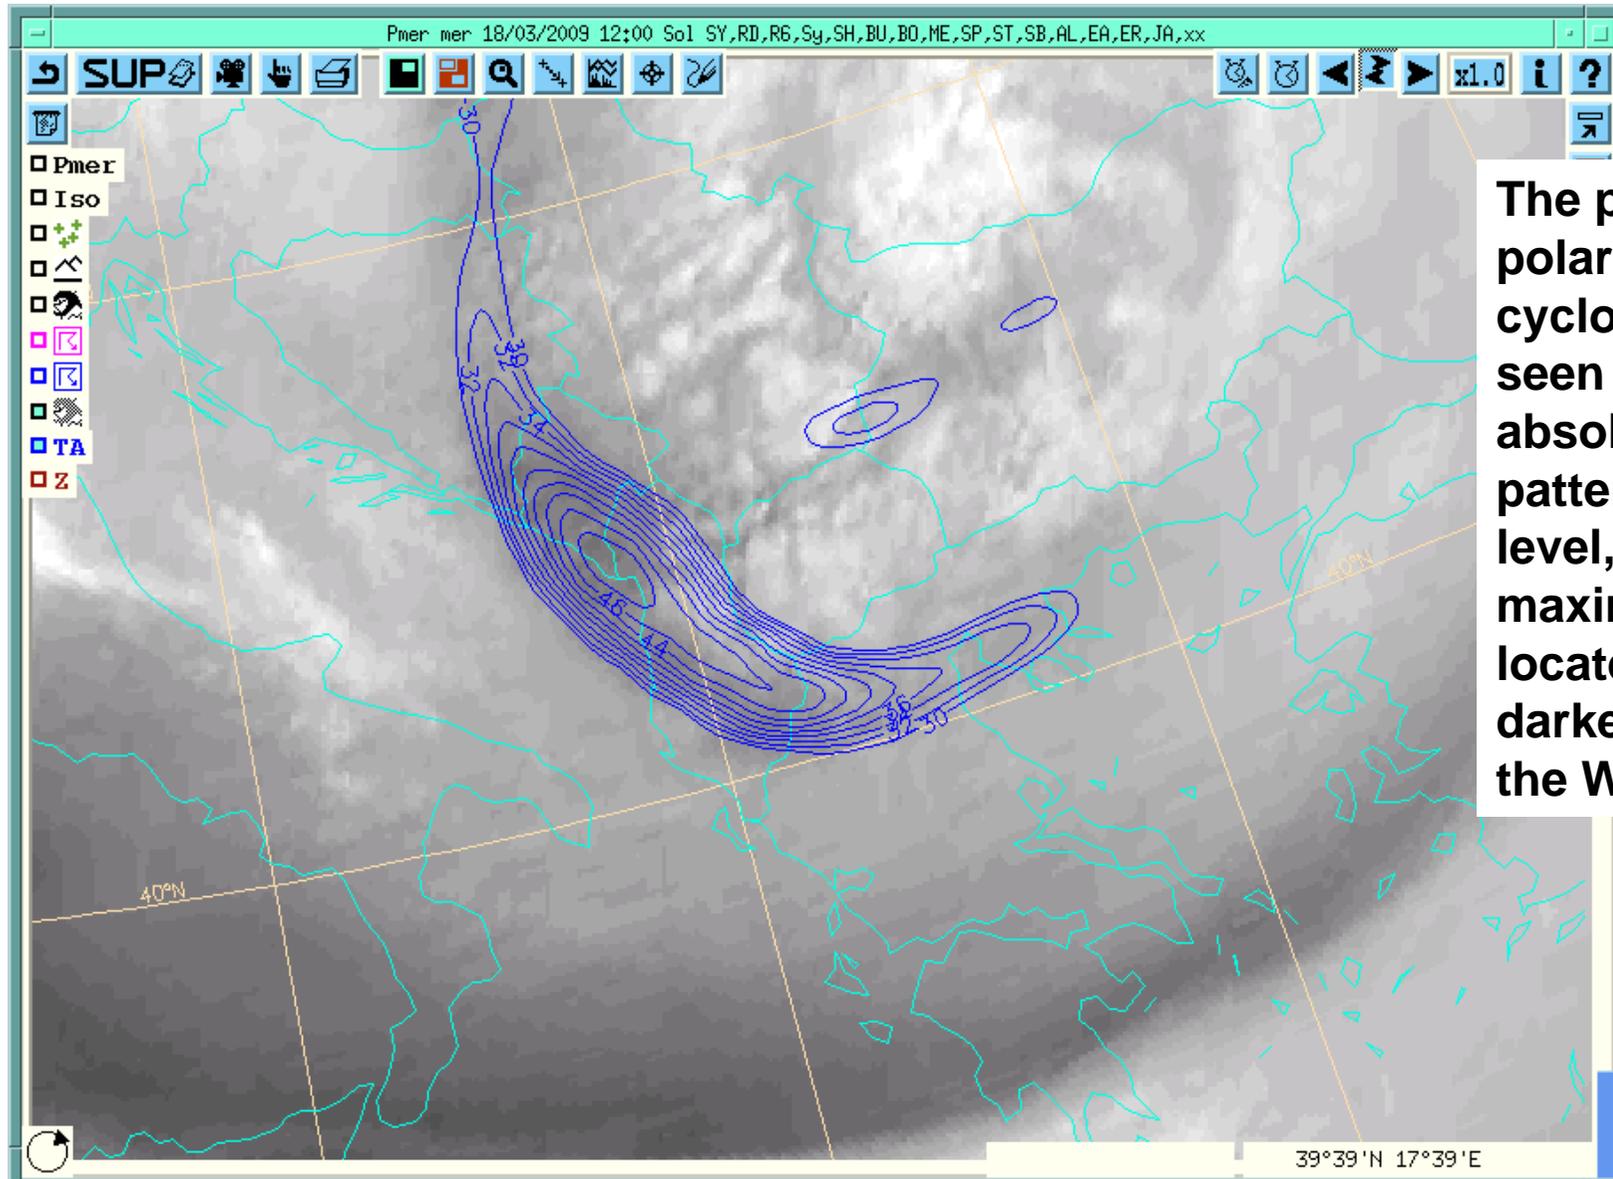

- WV image moisture boundary
- gradient zone of the dynamical tropopause height

### Low-level warm anomaly

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$ , 500 hPa Abs. vorticity (only > 30.10-5/s), 500 hPa heights

at 12 UTC

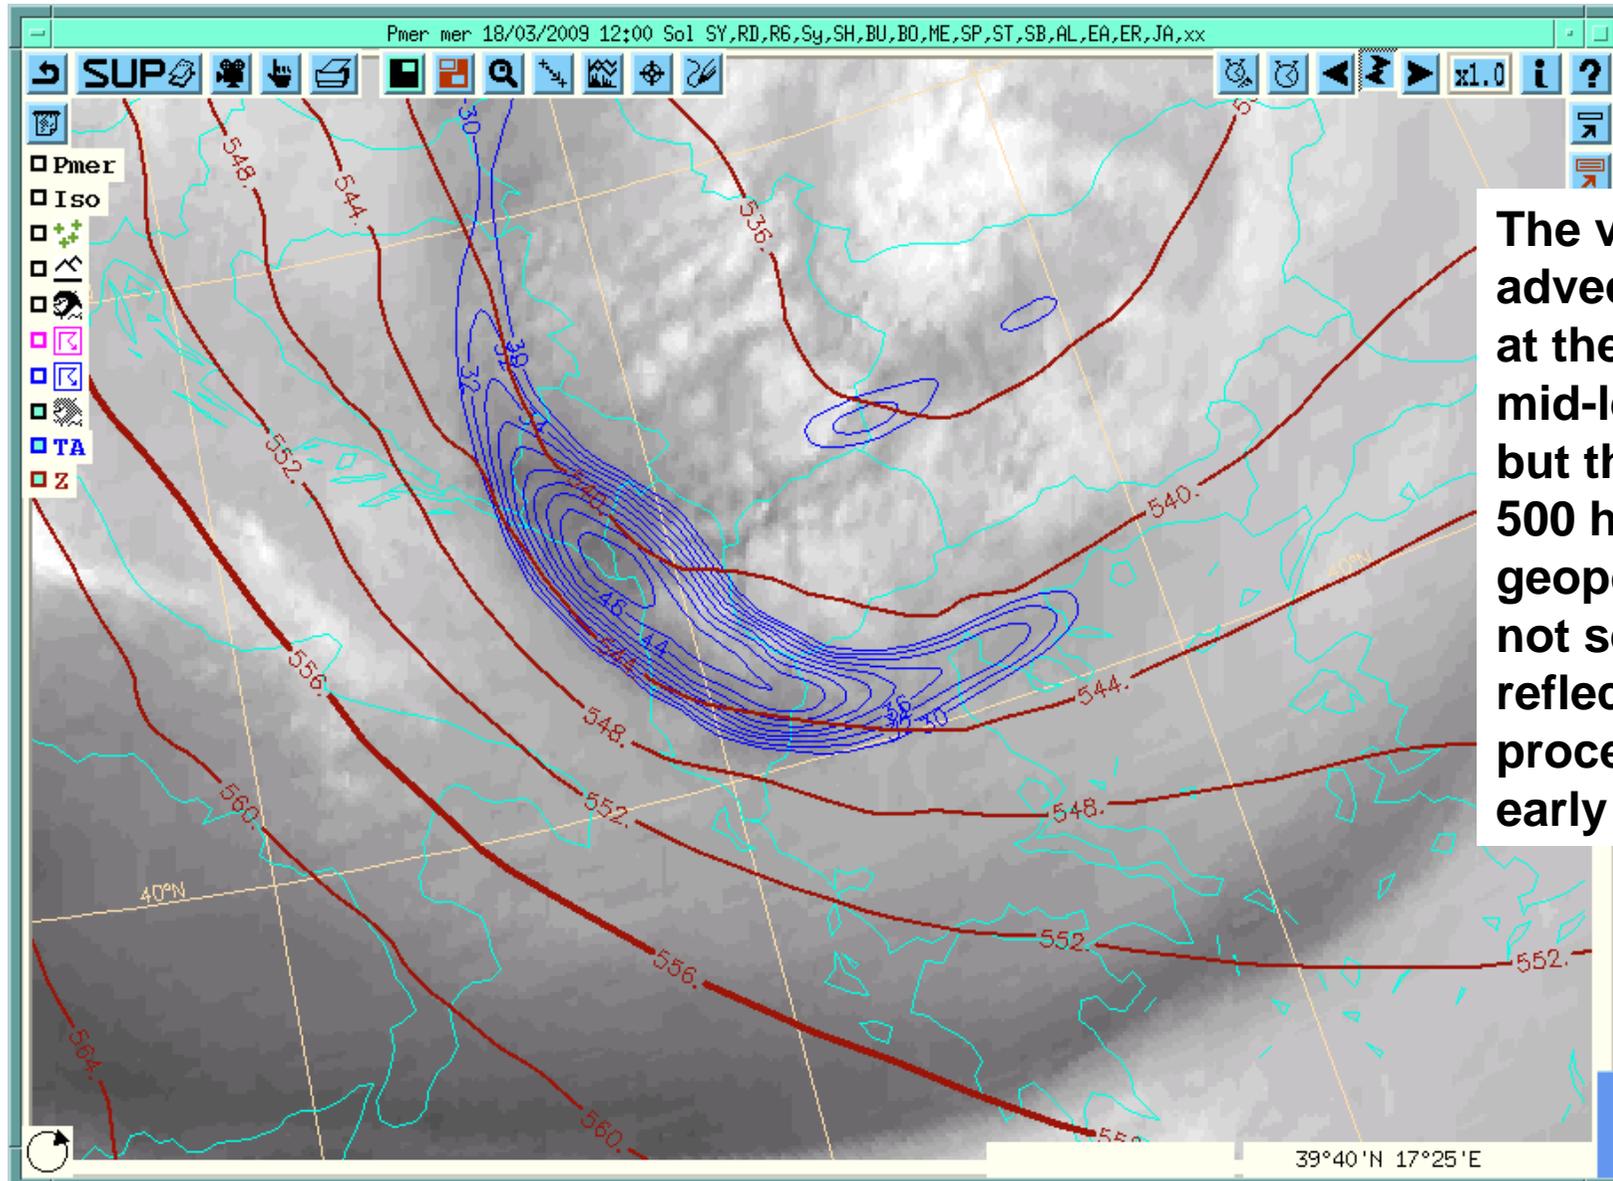

The potential for polar cyclogenesis is seen as a strong absolute vorticity pattern at mid-level, its maximum being located at the darkest part of the WV image.

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$ , 500 hPa Abs. vorticity (only > 30.10-5/s), 500 hPa heights

at 12 UTC

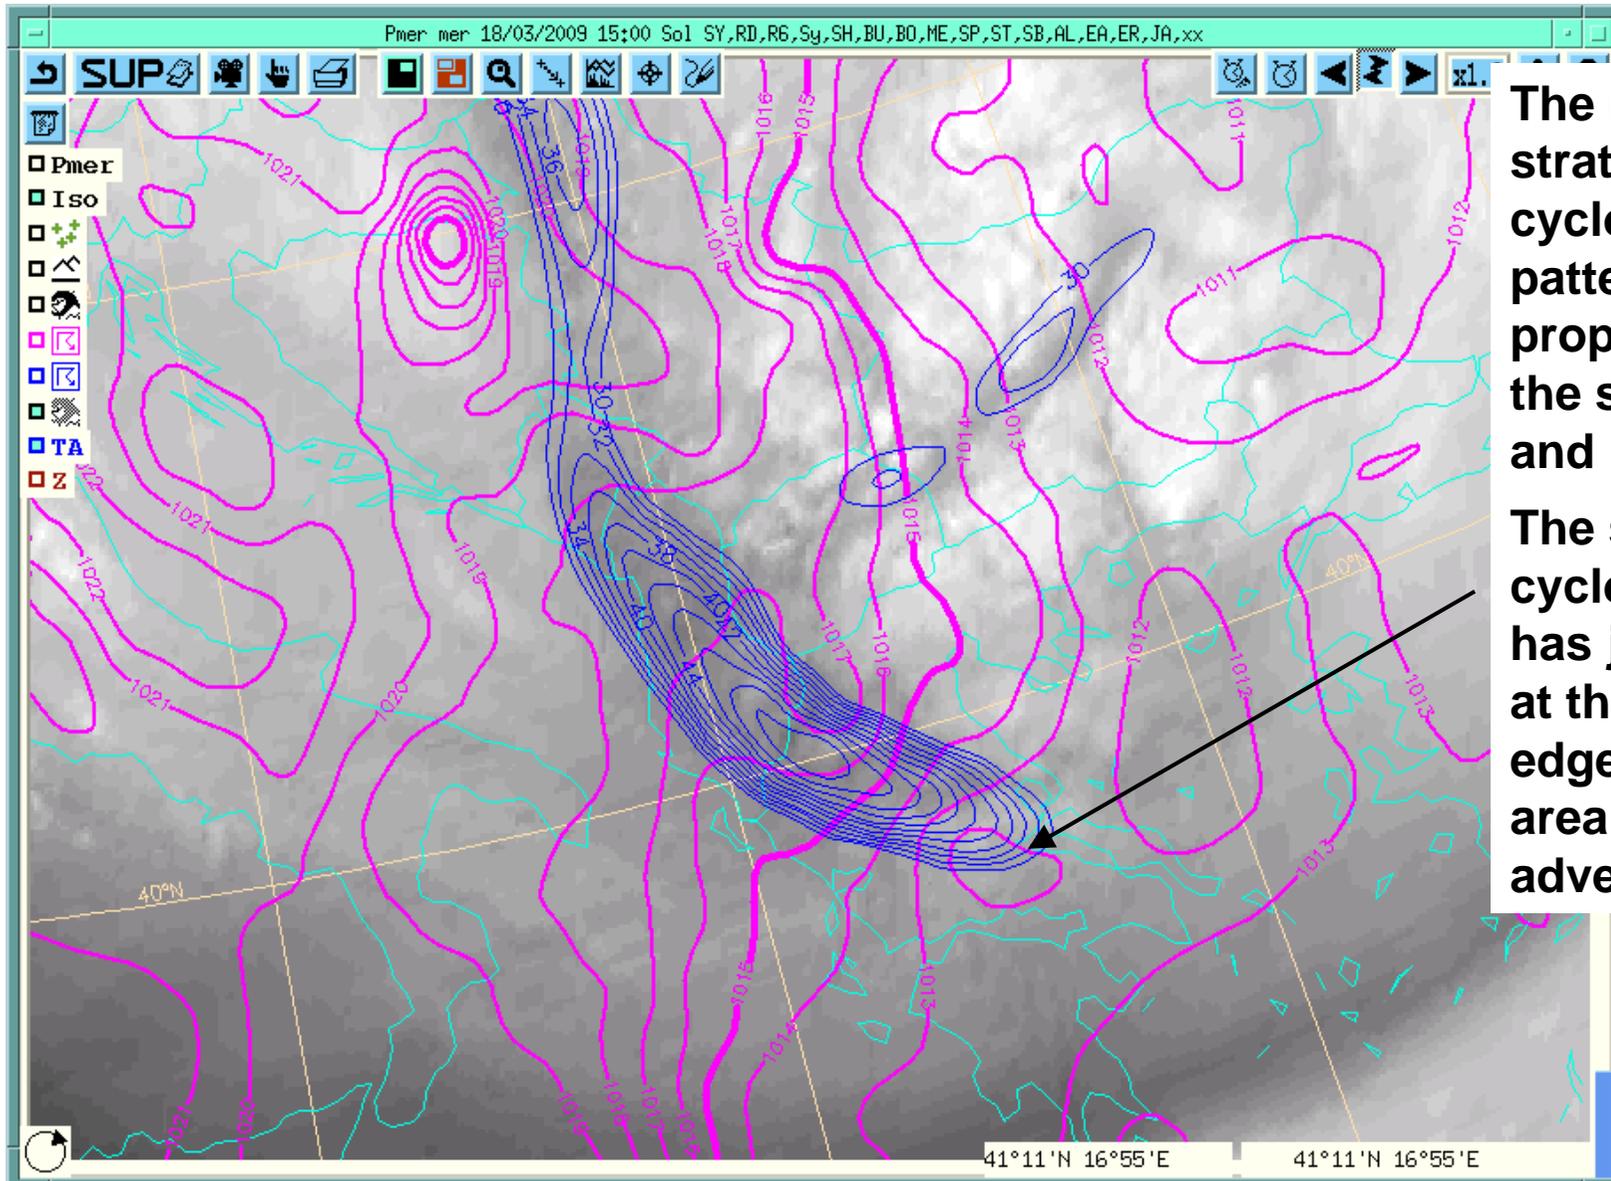

The vorticity advection occurs at the base of the mid-level trough, but the field of 500 hPa geopotential is not sensitive to reflect the process at an early stage.

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$ , 500 hPa Abs. vorticity (only  $> 30 \cdot 10^{-5}/\text{s}$ ), MSLP obs. (each 2 hPa)

at 15 UTC

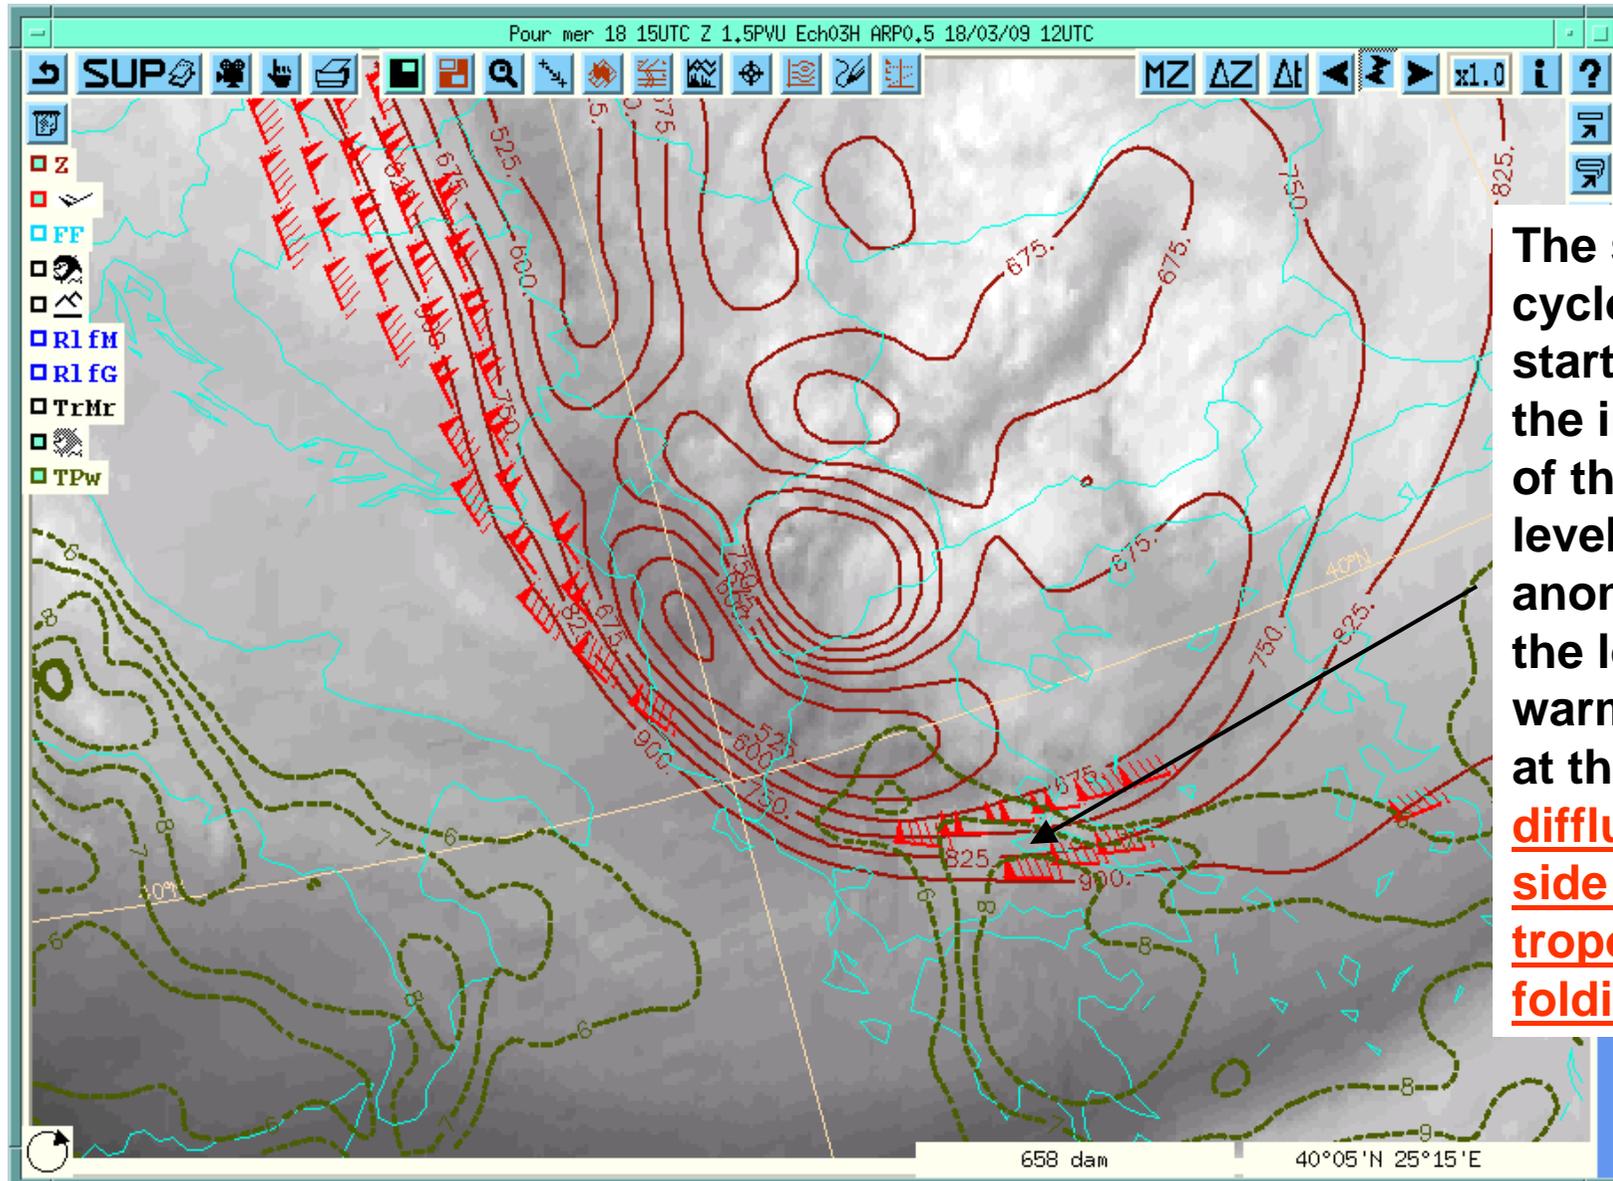

The upper-level stratospheric cyclonic vorticity pattern propagated to the south-east and

The surface cyclogenesis has just started at the leading edge of the area of vorticity advection

# Polar cyclogenesis over Eastern Mediterranean

6.2  $\mu\text{m}$ , 1.5 PVU heights (< 900 dam), 1.5 PVU wind (>90 kt), 850 hPa  $\theta_w$  (> 6  $^{\circ}\text{C}$ )

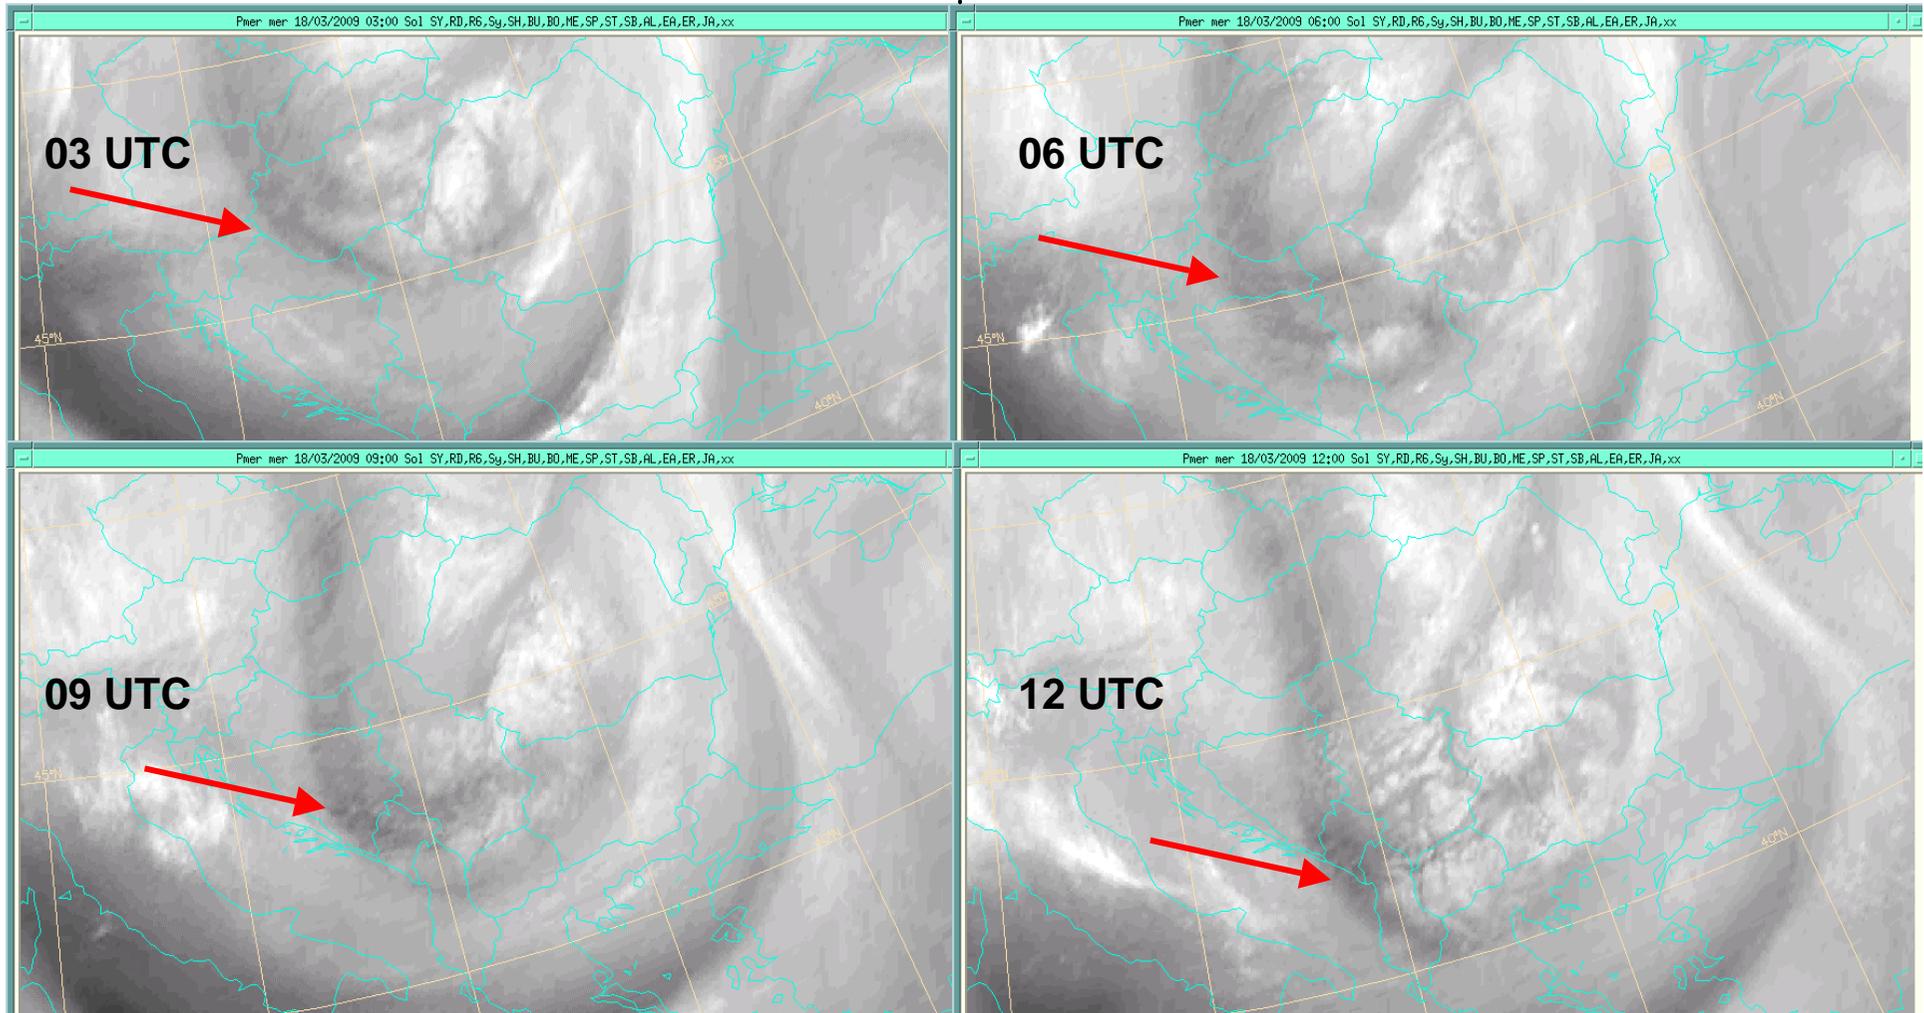

at 15 UTC

The surface cyclogenesis started after the interaction of the upper-level PV anomaly with the low-level warm anomaly at the leading diffluent-flow side of the tropopause folding.

# Polar cyclogenesis over Eastern Mediterranean

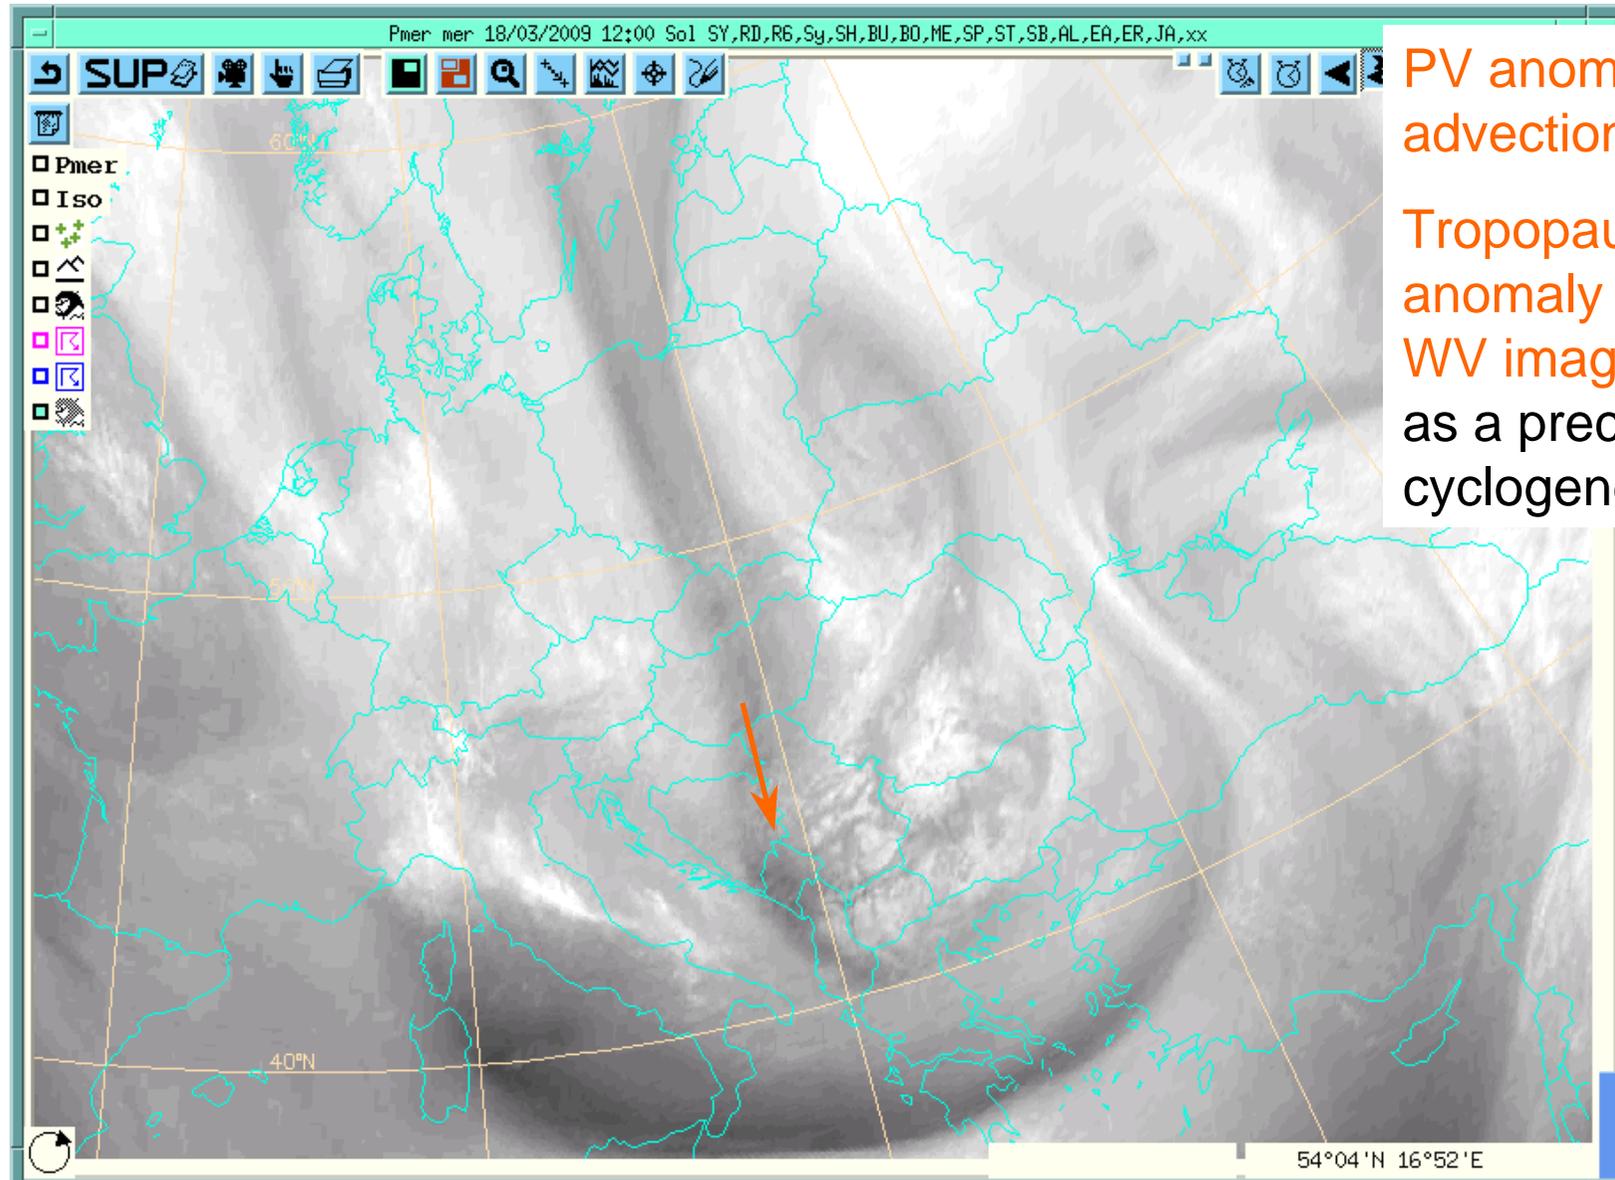

6.2  $\mu\text{m}$

The condition for the upper-level forcing is seen as a darkening dry zone in the sequence of 6.2  $\mu\text{m}$  WV image.

# **PV concept, jet stream analysis and cyclone development**

***Detection of NWP errors in dynamical  
model performance***

# NWP ERRORS

## WV imagery jet stream analysis

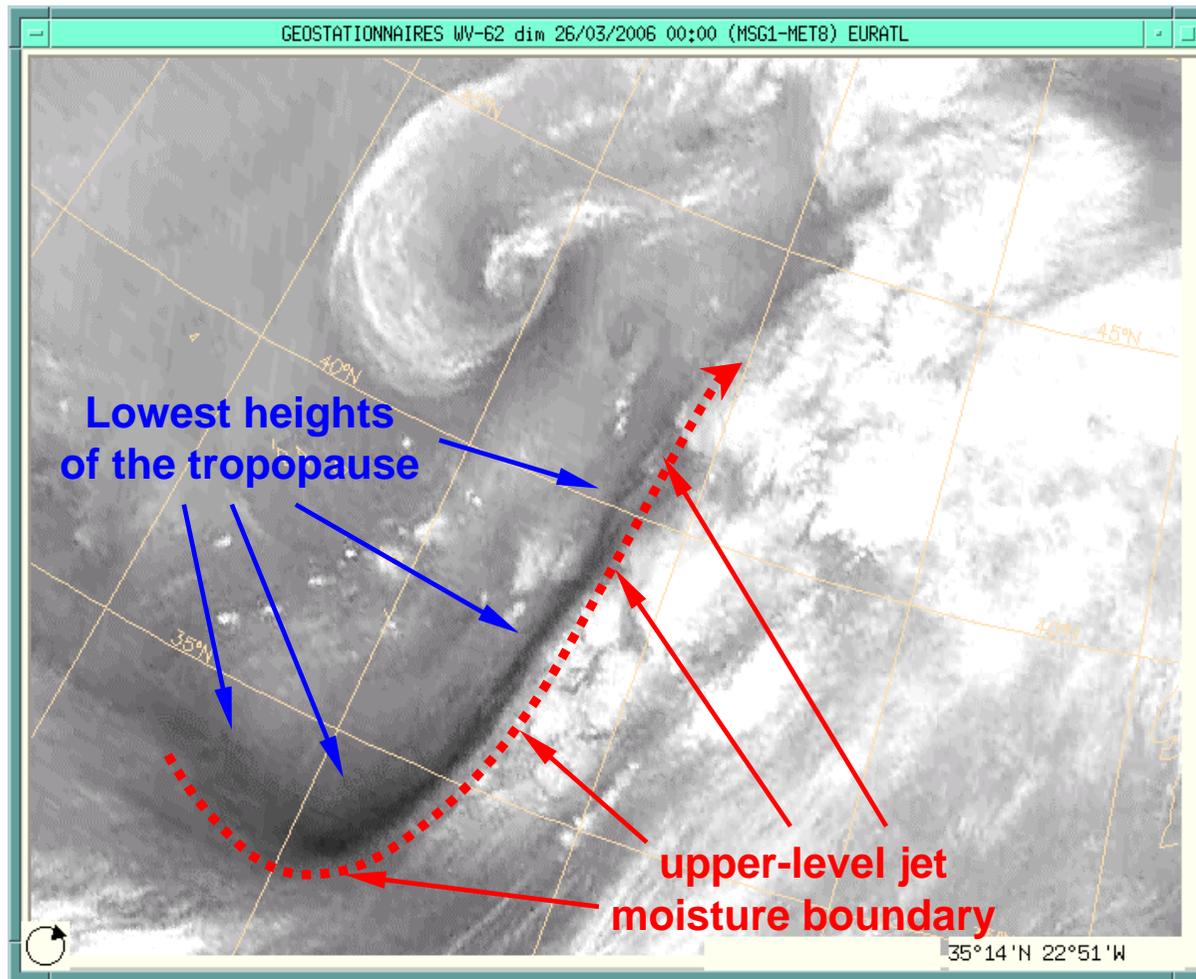

Applying WV imagery in 6.2  $\mu\text{m}$  channel and PV analysis provides with a basis of methods for check on the validity of NWP output and improving early forecasts (Santurette & Georgiev, 2005).

The dynamically active regions are marked by tropopause dynamic anomalies (or, equally, positive PV anomalies) and strengthening jets.

Looking at the 6.2  $\mu\text{m}$  image, indicate the position of the upper-level jet .

# NWP ERRORS

## WV imagery analysis

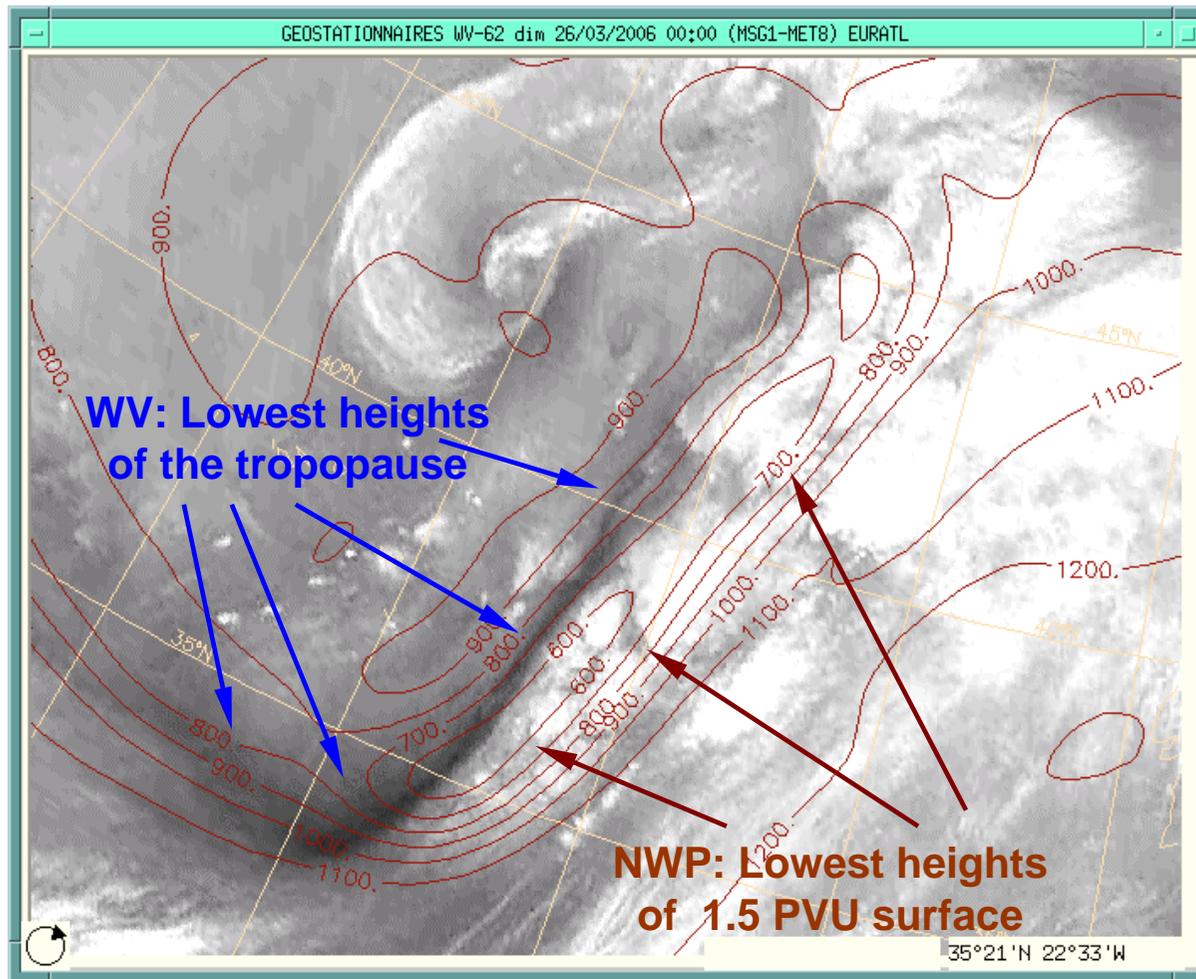

Applying WV imagery in 6.2  $\mu\text{m}$  channel and PV analysis provides with a basis of methods for check on the validity of NWP output and improving early forecasts (Santurette & Georgiev, 2005).

Dynamically active regions are marked by a tropopause dynamic anomaly (or, equally, positive PV anomaly) and strengthening of the jet

The jet stream corresponds to a strong dark/light gradient on the 6.2  $\mu\text{m}$  image with a dark zone of dry air related to a tropopause dynamic anomaly on the polar side of the jet .

# NWP ERRORS

## WV imagery PV analysis

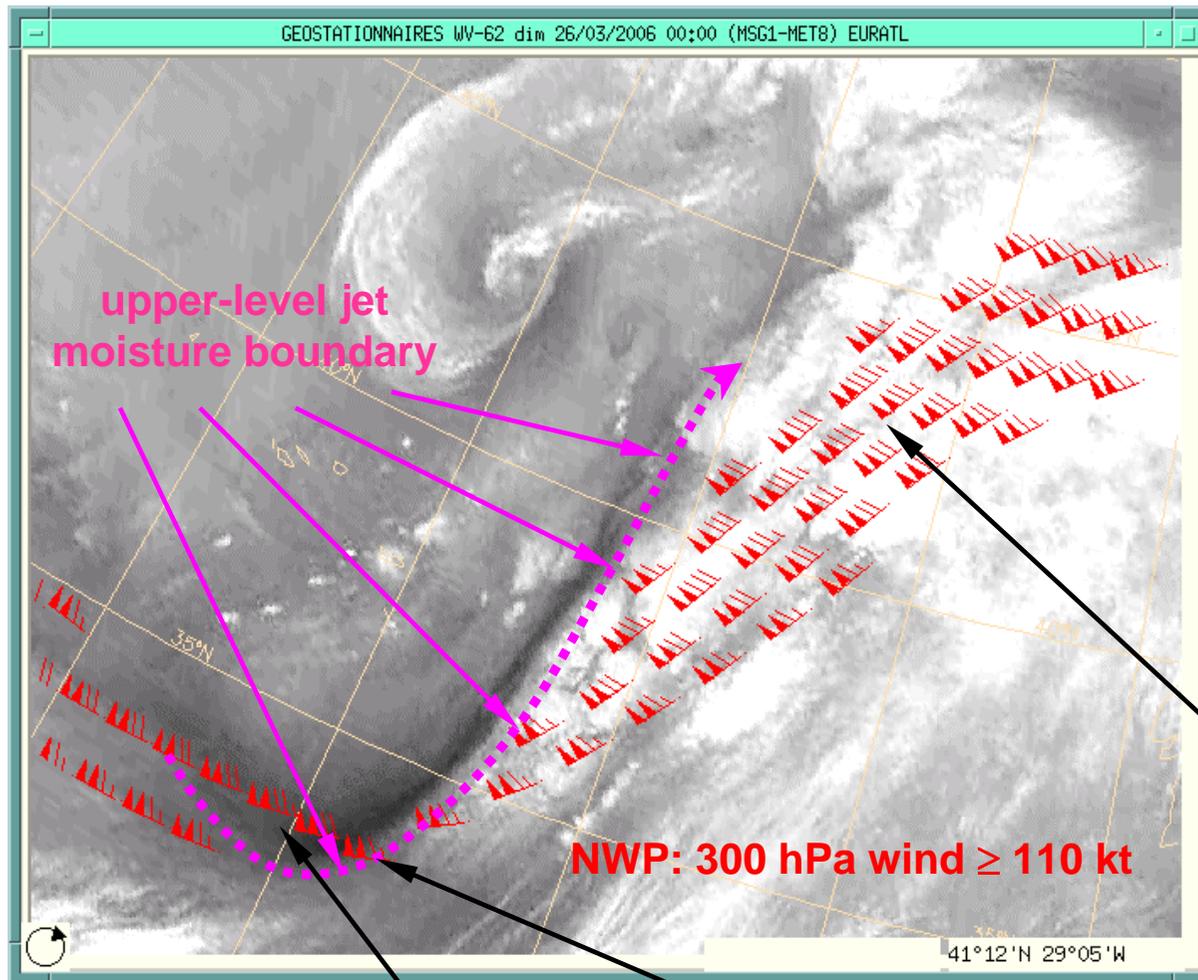

In the real atmosphere, shown by the satellite observations, the region of the lowest heights of the dynamical tropopause is located just rear to the darkest strip on the 6.2  $\mu\text{m}$  image .

In this case, the ARPEGE model analysis has the minimum heights of the 1.5 PVU surface further east of the dry zone of the stratospheric intrusion related to the dark area on the WV image.

**This mismatch is a sign for an error in the dynamical performance of the NWP model.**

# NWP ERRORS

## WV imagery jet stream analysis

*The error is clearly seen in the WV imagery jet stream analysis.*

In the real atmosphere, the jet corresponds to a strong dark/light gradient on the 6.2  $\mu\text{m}$  image with a dark zone on the polar side.

In this case, the ARPEGE model analysis has the jet further north-east of the WV boundary in the leading part of the trough.

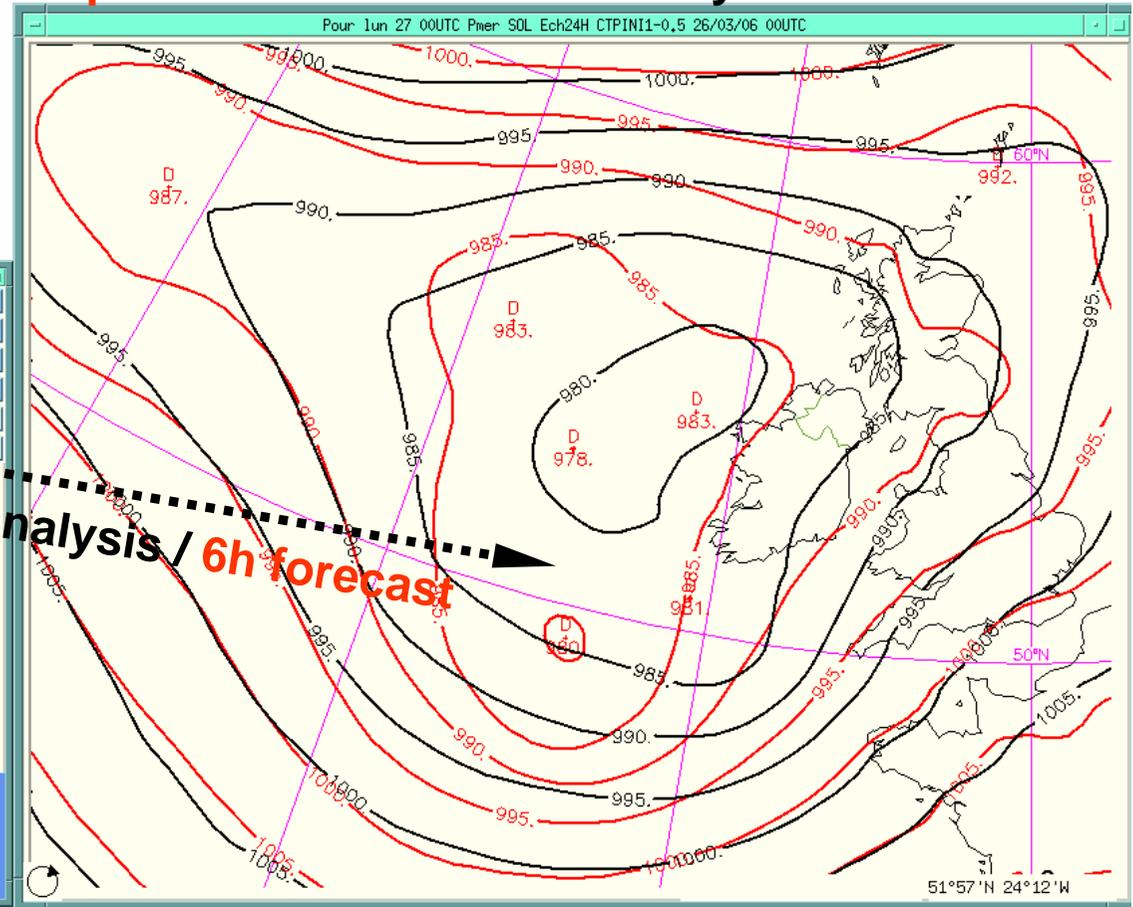

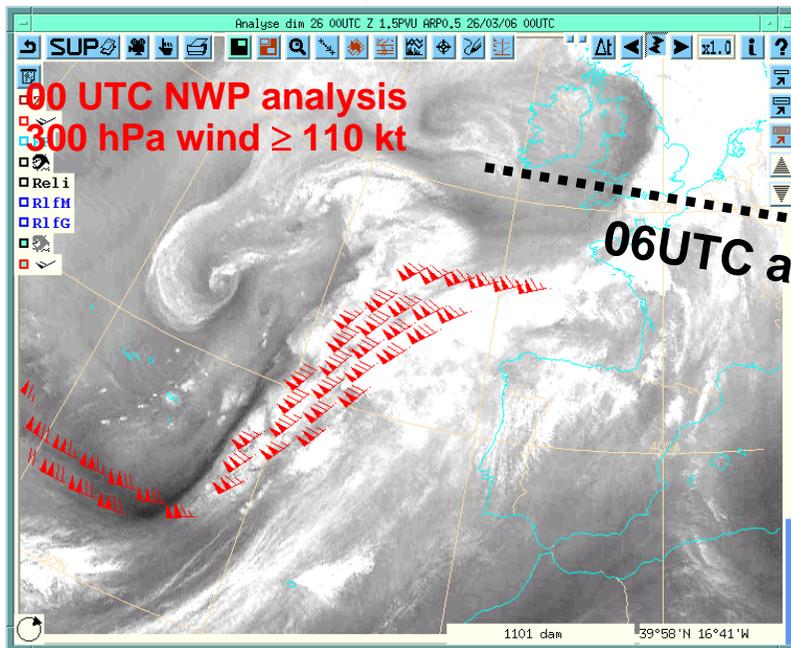

In the base of the trough, the wrong model performance sees the jet across the WV image dark stripe and then across the jet moisture boundary.

# NWP ERRORS

## WV imagery jet stream analysis

Operational NWP: MSLP analysis / 6h forecast

MSG 6.2  $\mu\text{m}$  channel

As a result,  
the operational NWP model did not predict correctly the cyclone  
development downstream the area of wrong jet stream numerical analysis.

## **6.2 $\mu\text{m}$ WV IMAGERY DIAGNOSIS**

### **MID-UPPER LEVEL ENVIRONMENT OF DEEP MOIST CONVECTION**

**A large portion of severe convective weather occurs in synoptic disturbances where upper-level synoptic-scale forcing mechanisms act in addition to a conditional instability of the atmosphere. There is an association between large-scale systems and moist deep convection (Doswell, 1987).**

**The forecasters can diagnose the upper-troposphere forcing for vertical motion by looking at the WV imagery patterns related to PV anomalies, jet streams, diffluent (divergent) flow.**

## **6.2 $\mu\text{m}$ WV IMAGERY DIAGNOSIS**

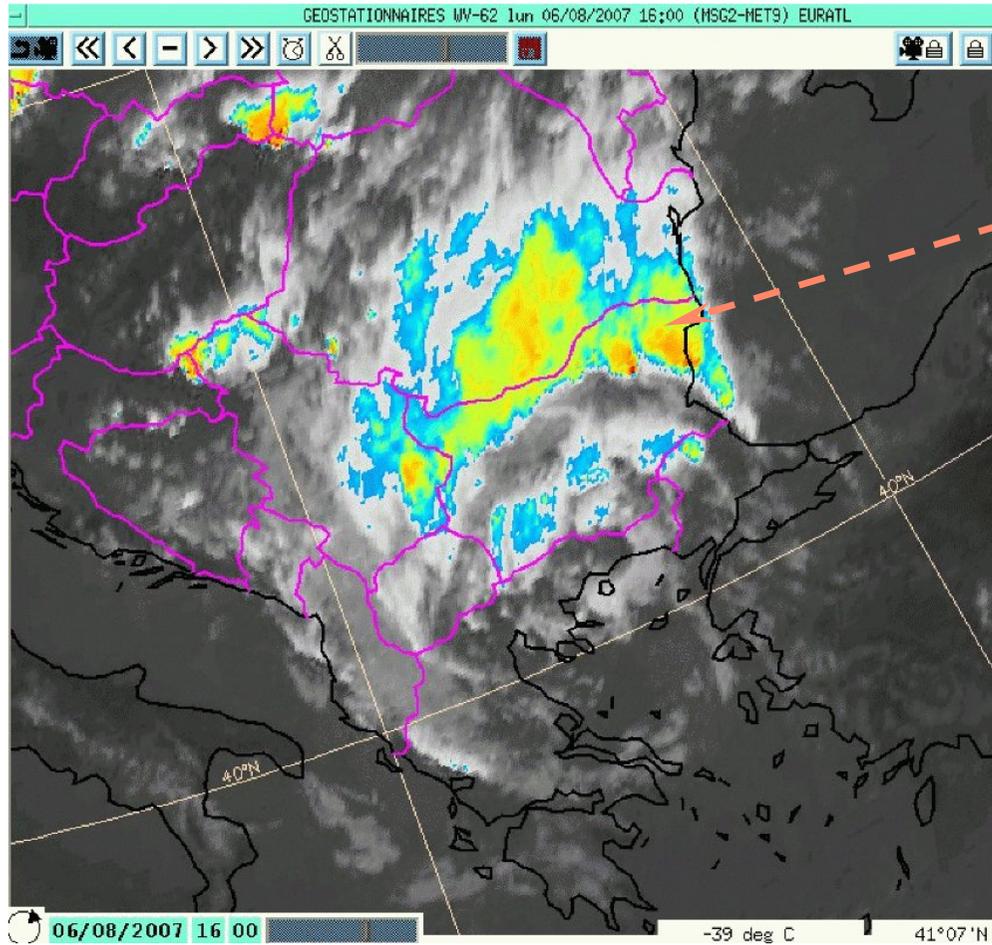

**Deep moist convection in  
blocking regime**

# **Animation 1**

# DEEP MOIST CONVECTION IN BLOCKING REGIME

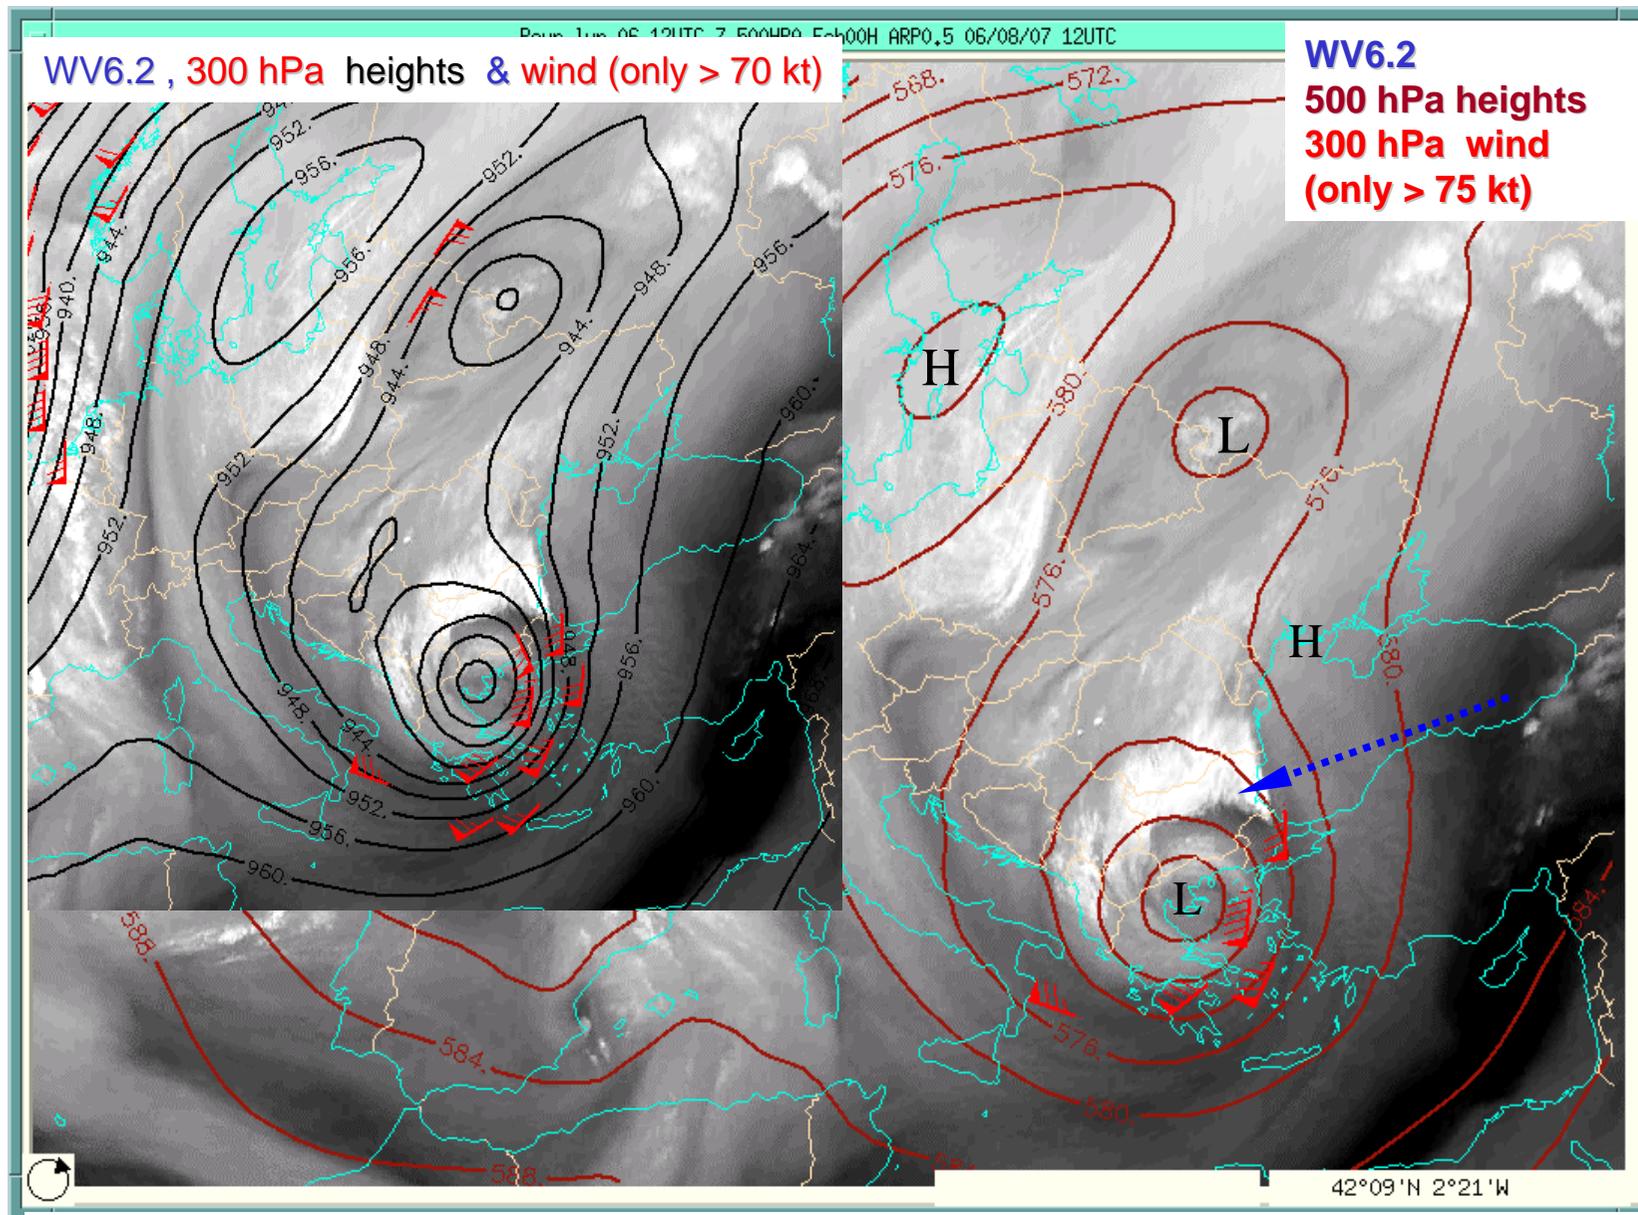

06 August 2007

MSG IR 10.8, colored brightness temperature < - 40 °C

The process developed in a strong blocking regime that can generate conditions for severe weather over the same area for a long time.

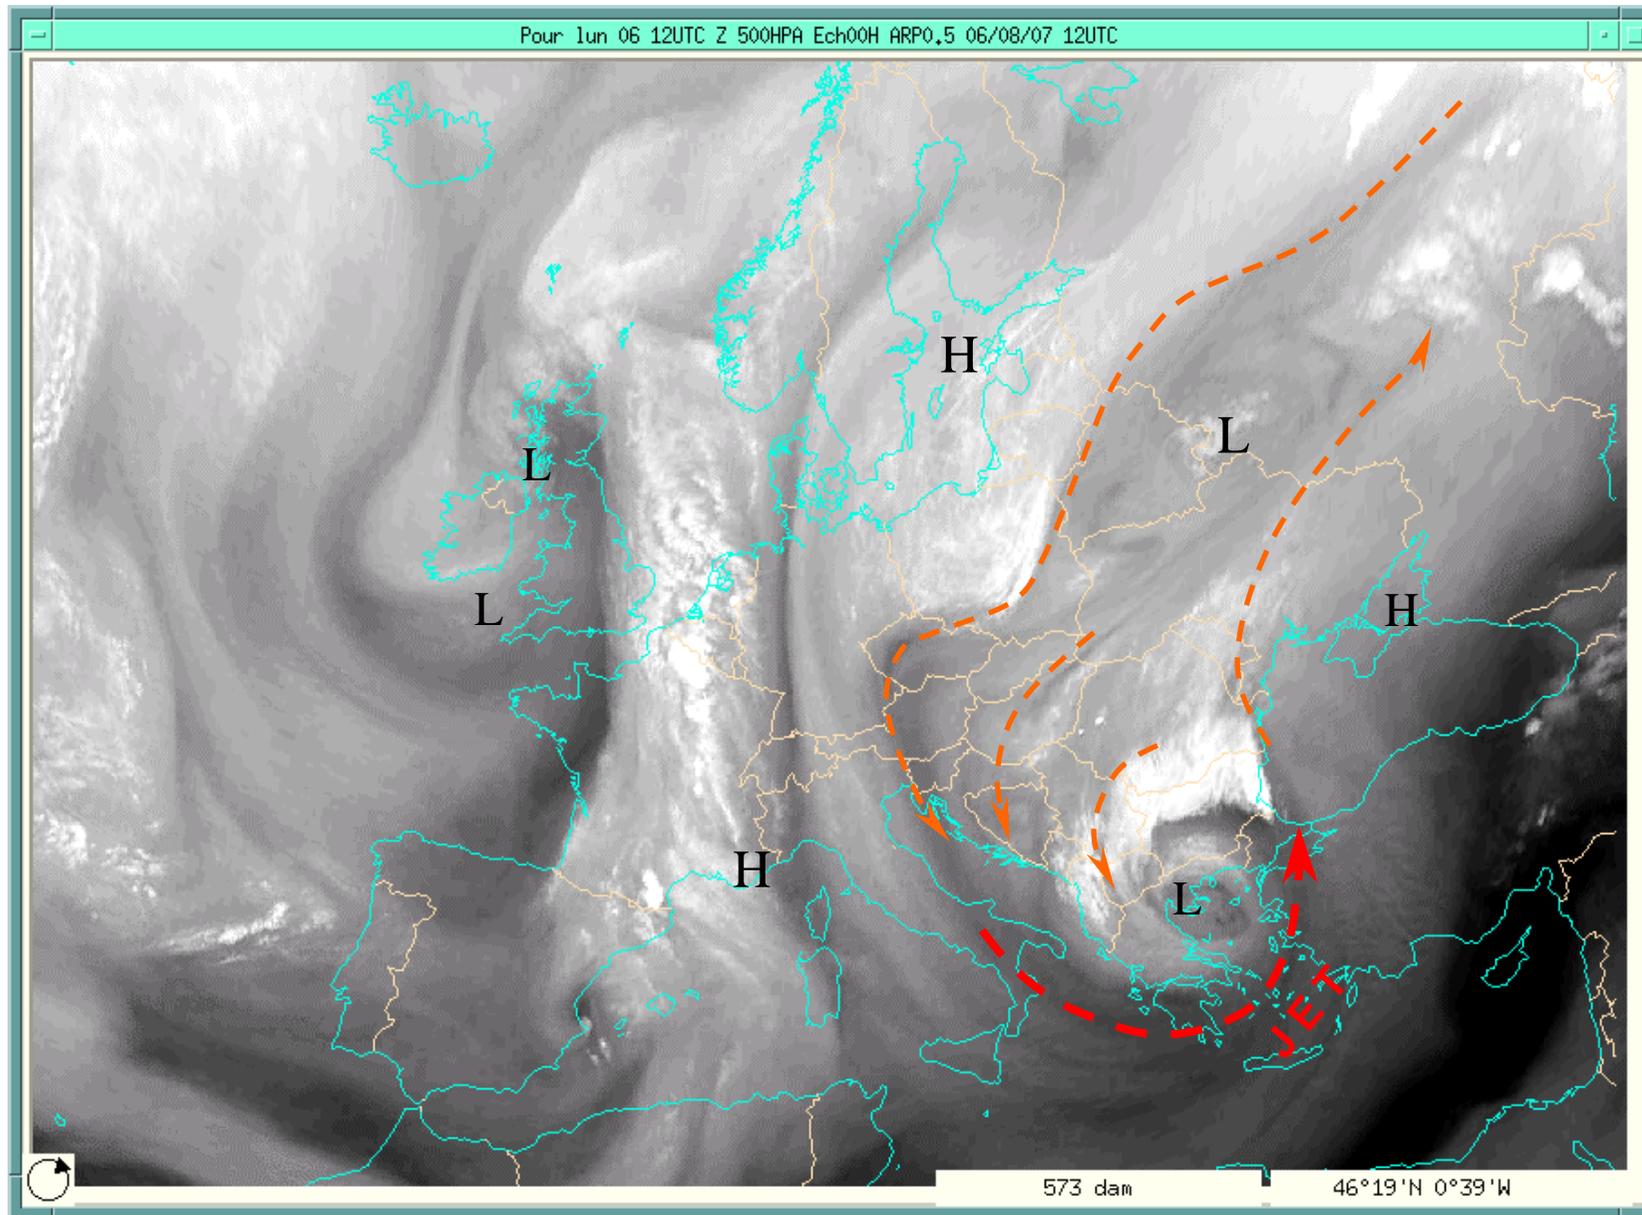

# UPPER-LEVEL ISOBARIC ANALYSIS

Diagnosis of upper-level forcing by satellite WV imagery:  
Divergent flow at the left exit of the upper-level jet in blocking circulation (Carroll, 1997).

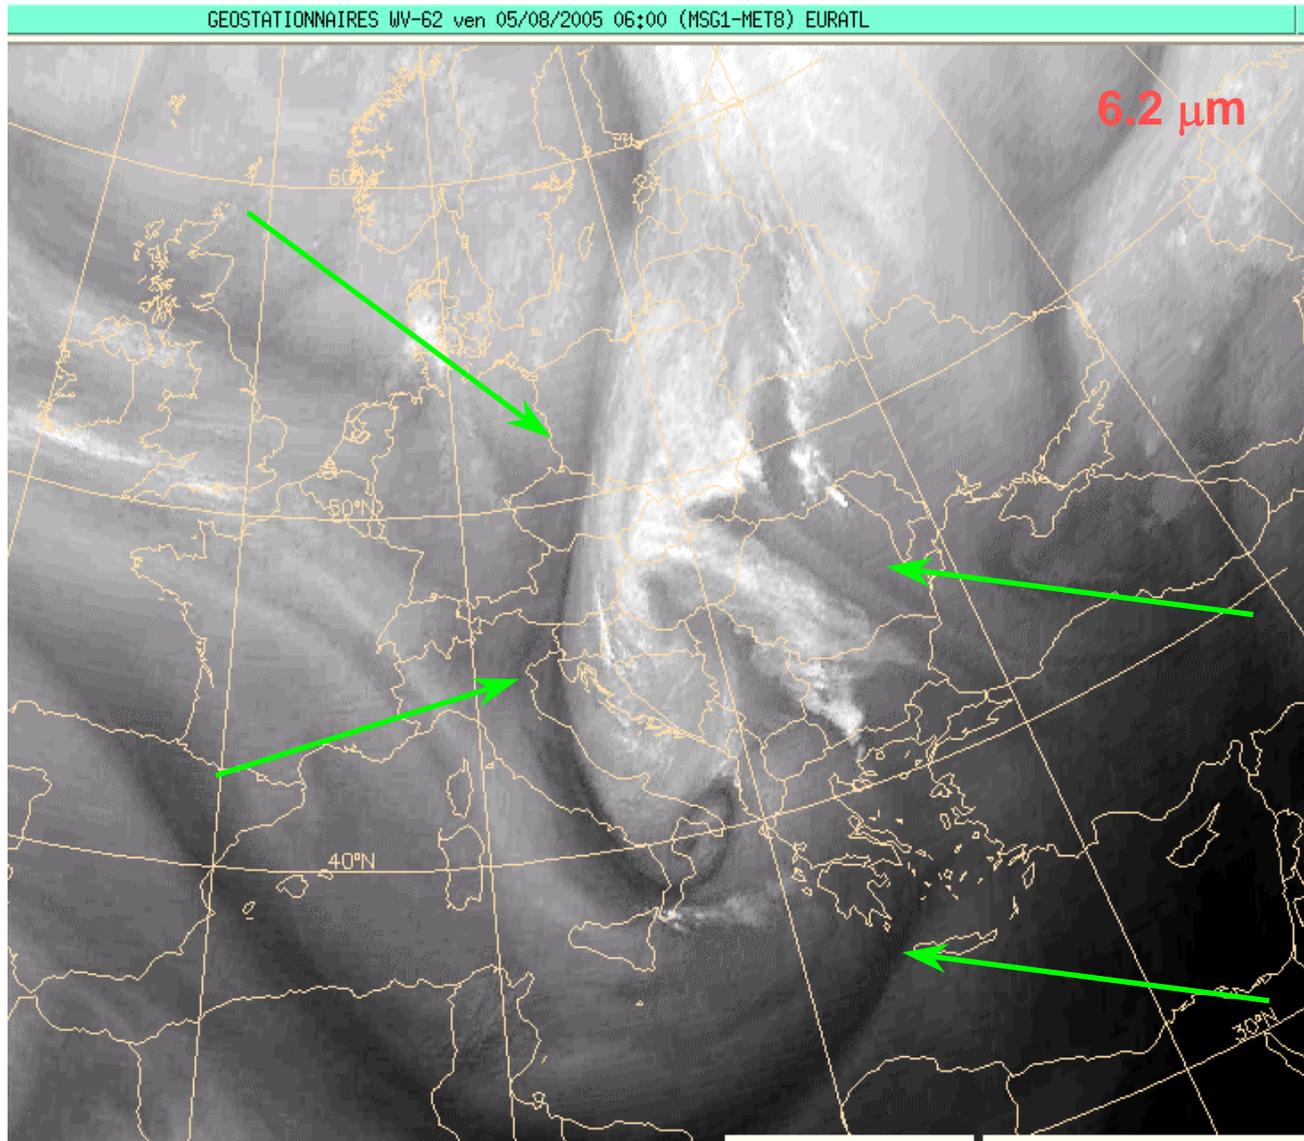

# UPPER-LEVEL FLOW

06 August 2007 Flash flood in Bulgaria

In a 6.2  $\mu\text{m}$  image, the moisture boundaries are parallel to the flow between upper-level high and low systems. This helps in recognition of the circulation patterns.

# FORCING OF CONVECTION IN BLOCKING REGIME

**5 August 2005**  
**Flash floods in Bulgaria**

**Blocking regime

6.2  $\mu\text{m}$

5 August 2005 06 UTC

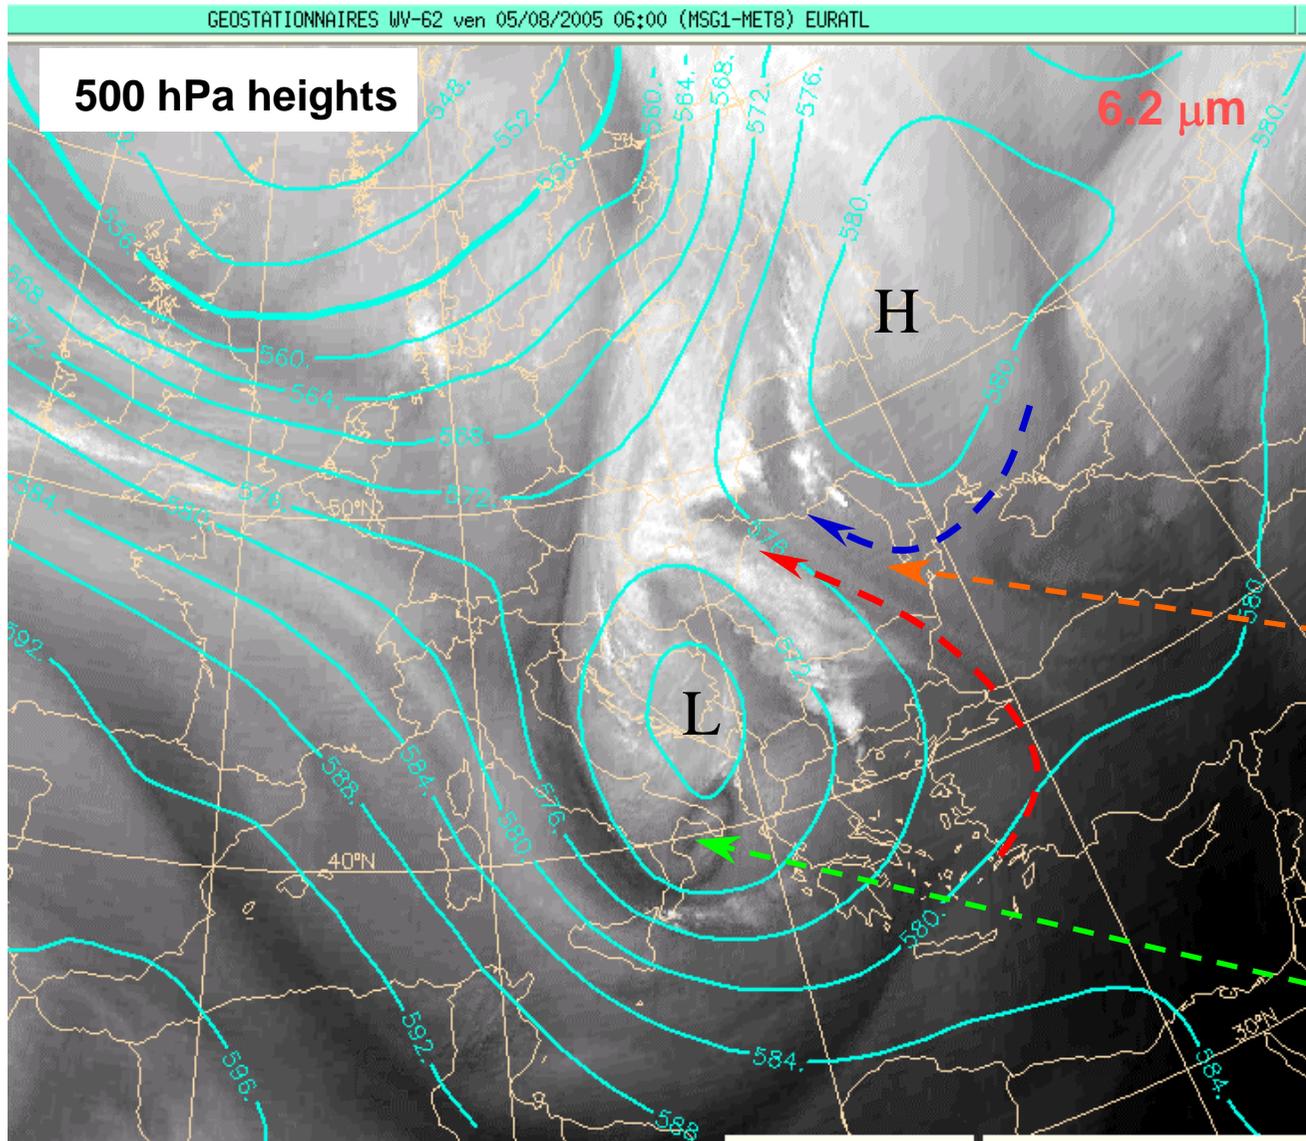

Look at the moisture boundaries in WV imagery 6.2  $\mu\text{m}$  for recognition of

**Blocking regime:**  
Synoptic-scale easterly winds.

Upper-level  
**VORTICITY** structure advected with the jet into the blocking circulation.

# ISOBARIC SURFACE ANALYSIS

*5 August 2005 06 UTC*

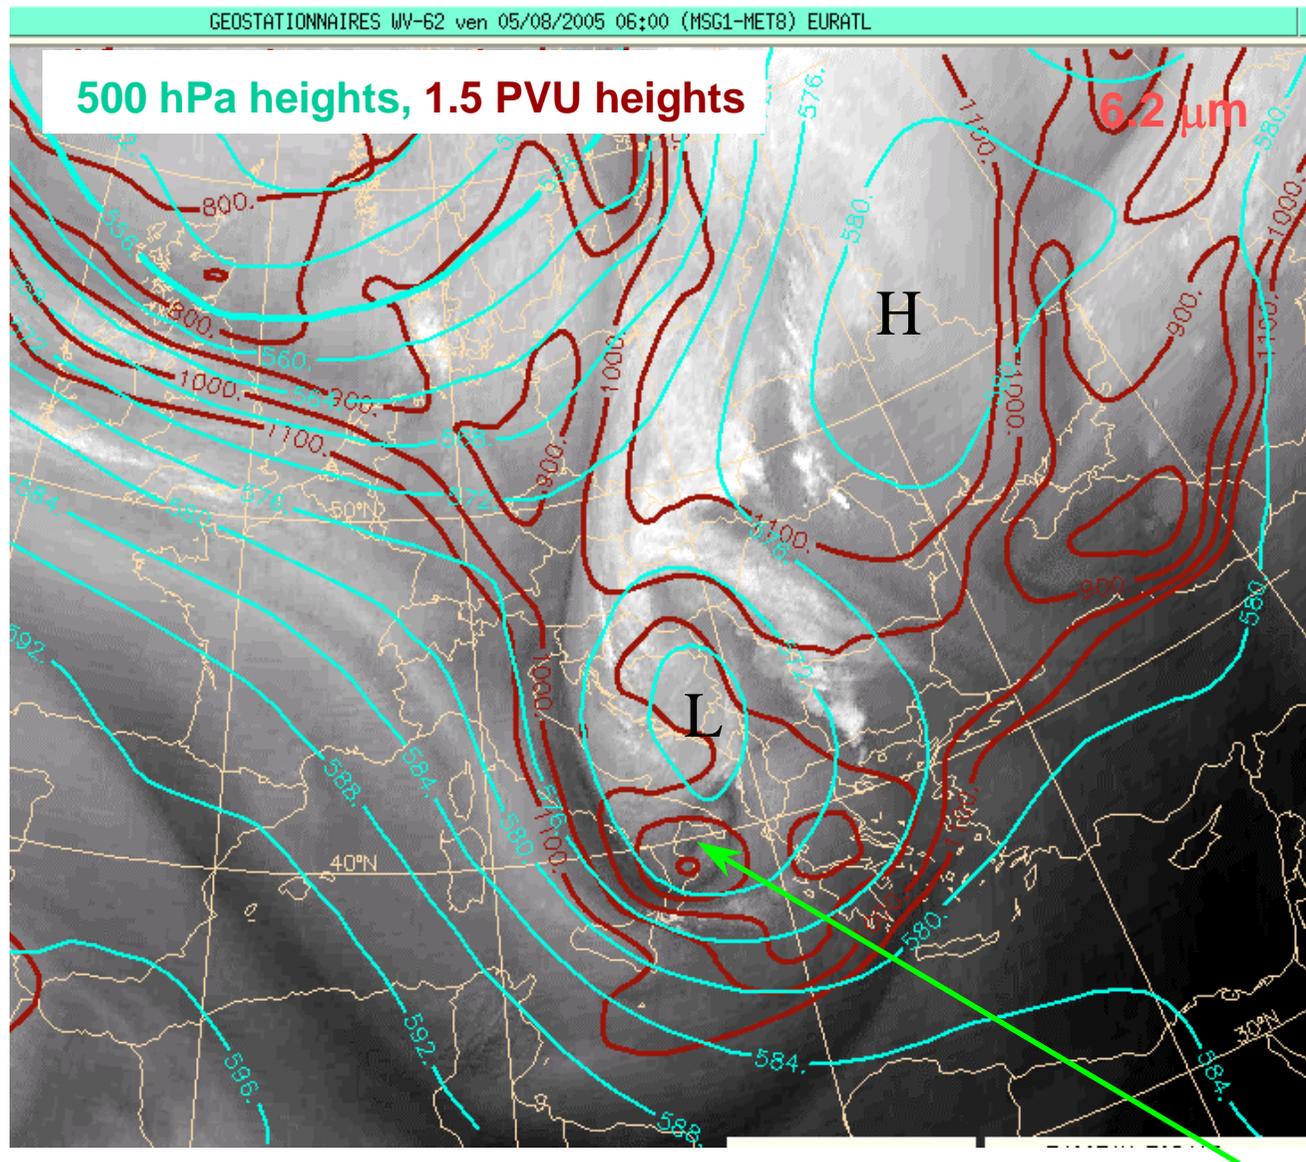

**Blocking regime:**  
Synoptic-scale  
easterly winds.

Upper-level VORTICITY  
structure **not visible**  
**through Isobaric**  
**Surface Analysis.**

It is obvious that the Diagnosis based on the 6.2 WV Imagery Analysis is much more efficient than using 500 hPa Isobaric Surface analysis, which does not provide a signal for an important vorticity feature of the upper-level dynamics.

# ISOBARIC SURFACE ANALYSIS

5 August 2005 06 UTC

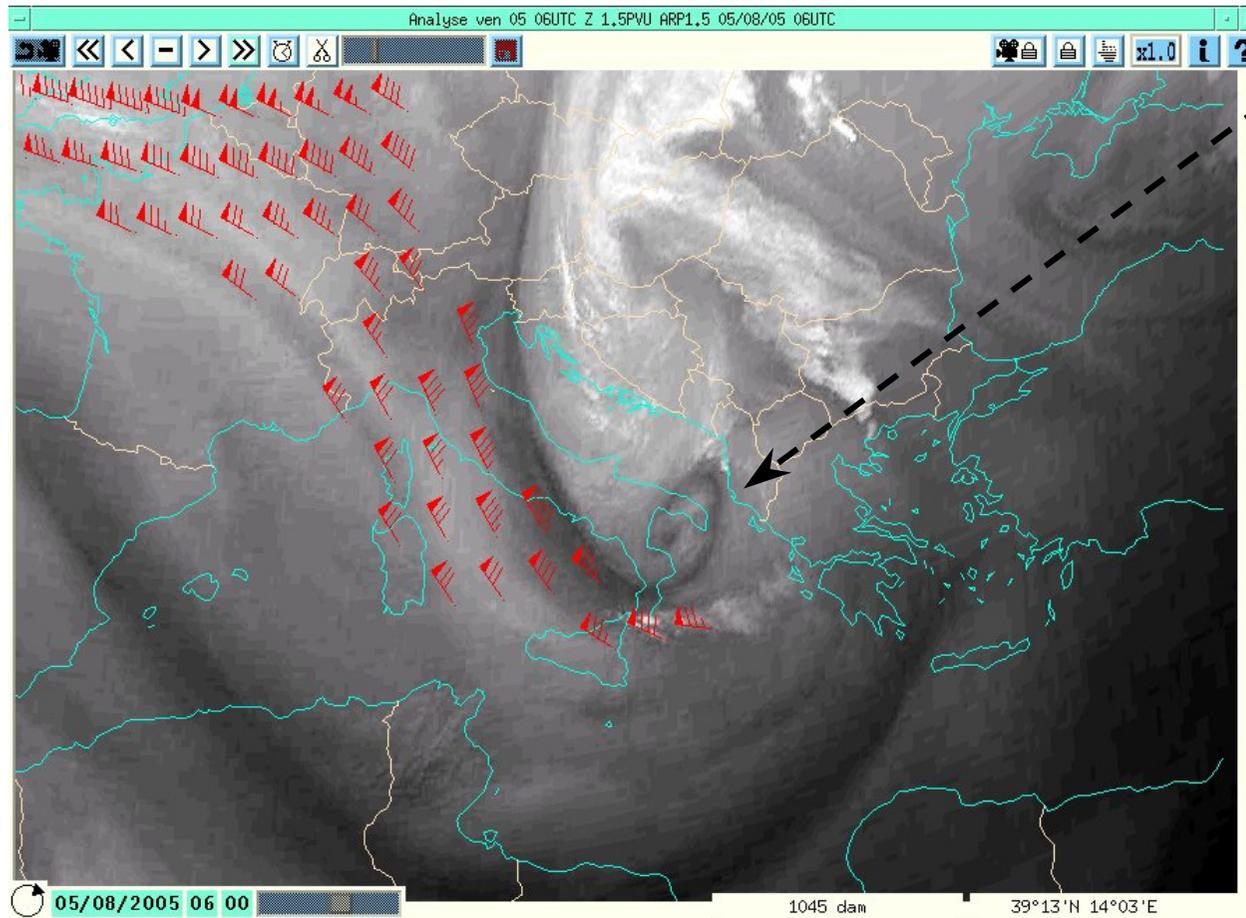

The inspection of the blocking regime provides knowledge of the related pre-convective upper-level environment :

- ✓ Left exit of a jet
- ✓ Dry intrusion and convective instability
- ✓ Vorticity advection over the same area for a long time

Upper-level VORTICITY structure is well seen as a PV anomaly (minimum height of the dynamical tropopause and a dark dry/vorticity feature on the WV image).

## PV anomaly advection

## *PV analysis*

WV6.2

1.5 PVU wind  
(only > 65 kt)

A PV anomaly is always seen in the WV images, being a conservative Dynamic dry zone

(detected in the WV imagery more than 24 hours before the forcing of deep convective development).

Animated WV imagery show the evolution of the Dynamic dry zone and related patterns:

- PV anomaly advection, related to a jet (especially in blocking upper-level circulation ),
- Probability for intensive convection in the leading diffluent-flow side of a PV anomaly .

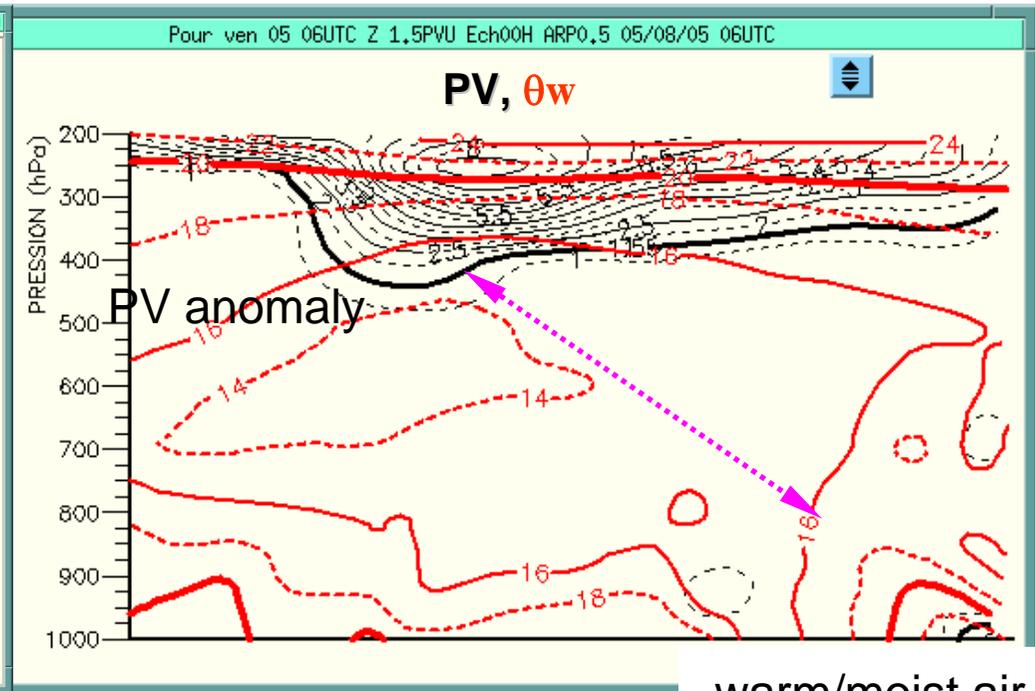

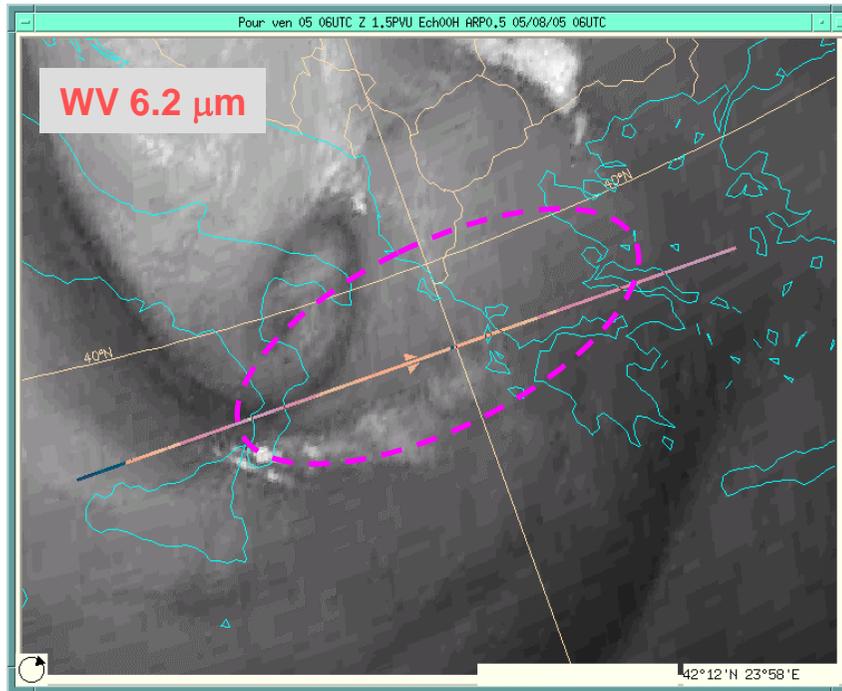

## **Animation 2**

***Upper level forcing  
for vertical motion:***

PV forecast  
(ARPEGE)*

*Mismatch between the  
dynamical tropopause  
folding simulated by the  
NWP model and the  
vorticity pattern on the  
WV image*

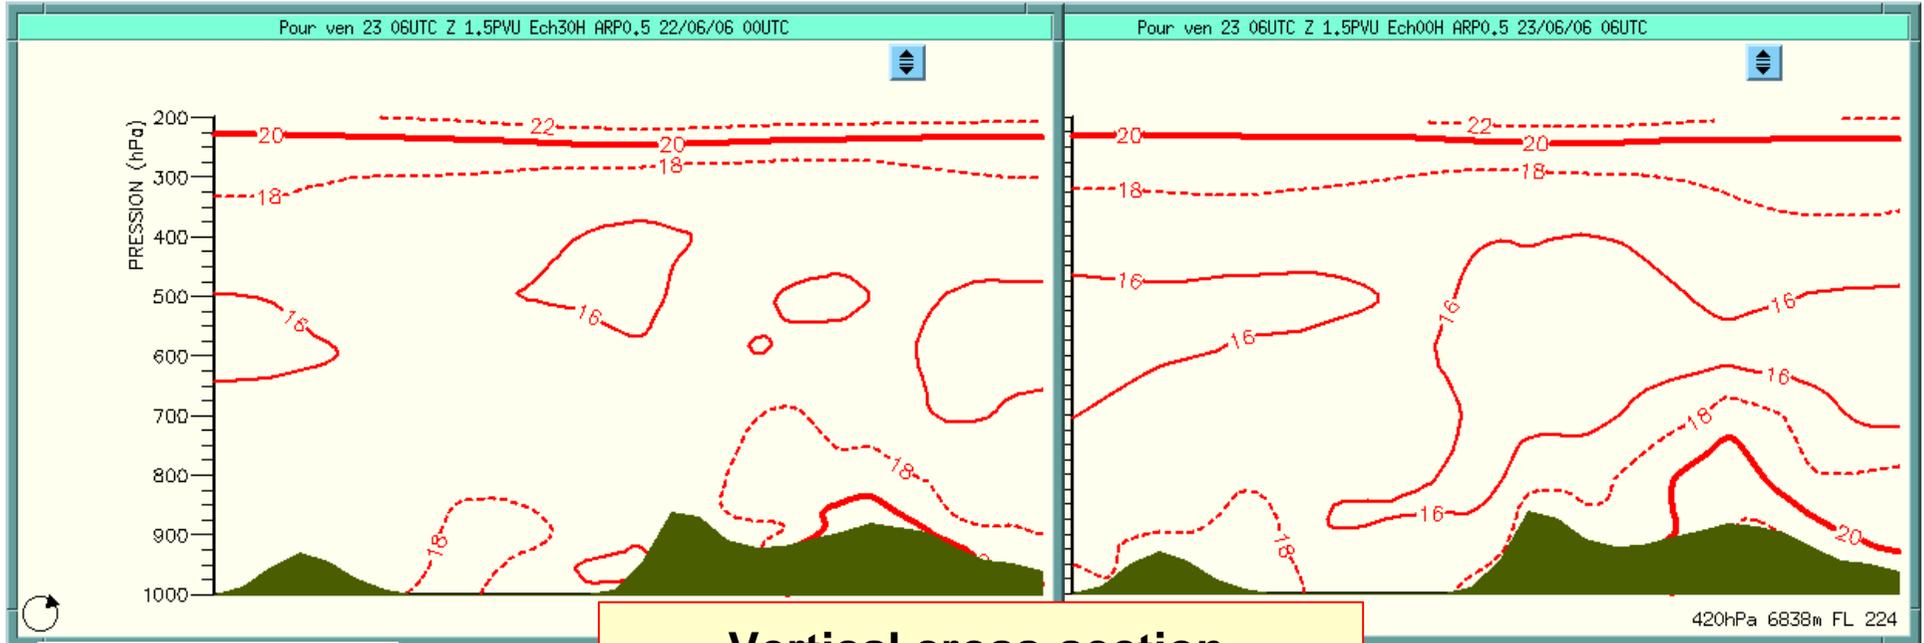

The area of the minimum height of 1.5 PVU surface (the dynamical tropopause) in the 30 h ARPEGE forecast (975 dam contour) does not mirror the specific dark vorticity feature on the WV image (Georgiev & Kozinarova, 2009).

# Low-level perspective

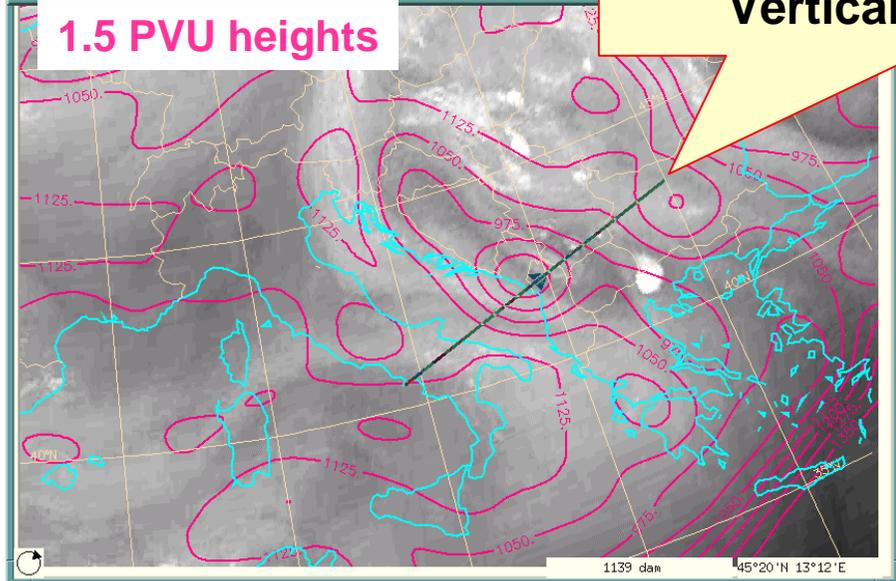

06 UTC 23 June 2006

30 h forecast of  $\theta_w$

Analysis of  $\theta_w$

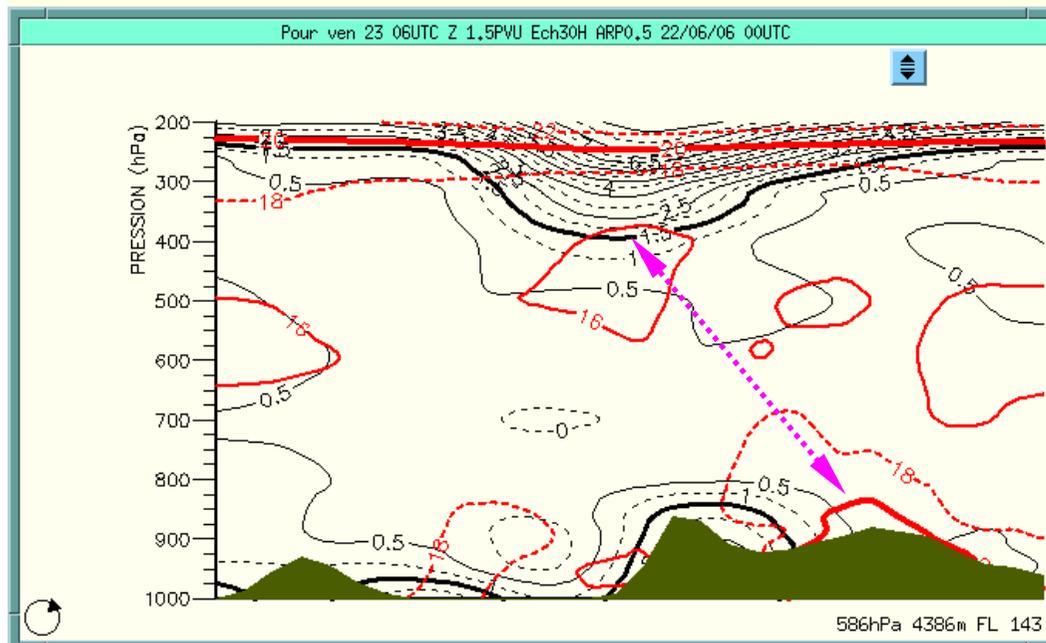

Vertical cross-section

*Thermodynamic analysis of the wrong NWP forecast.*

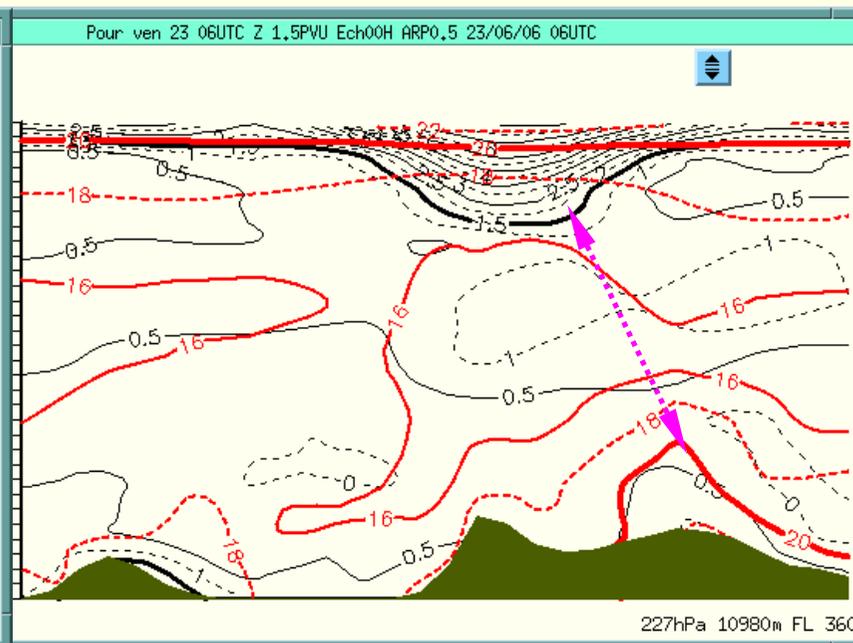

## *Upper and low-level perspective*

**30 h forecast of  $\theta_w$  and PV**

**06 UTC 23 June 2006**

**Analysis of  $\theta_w$  and PV**

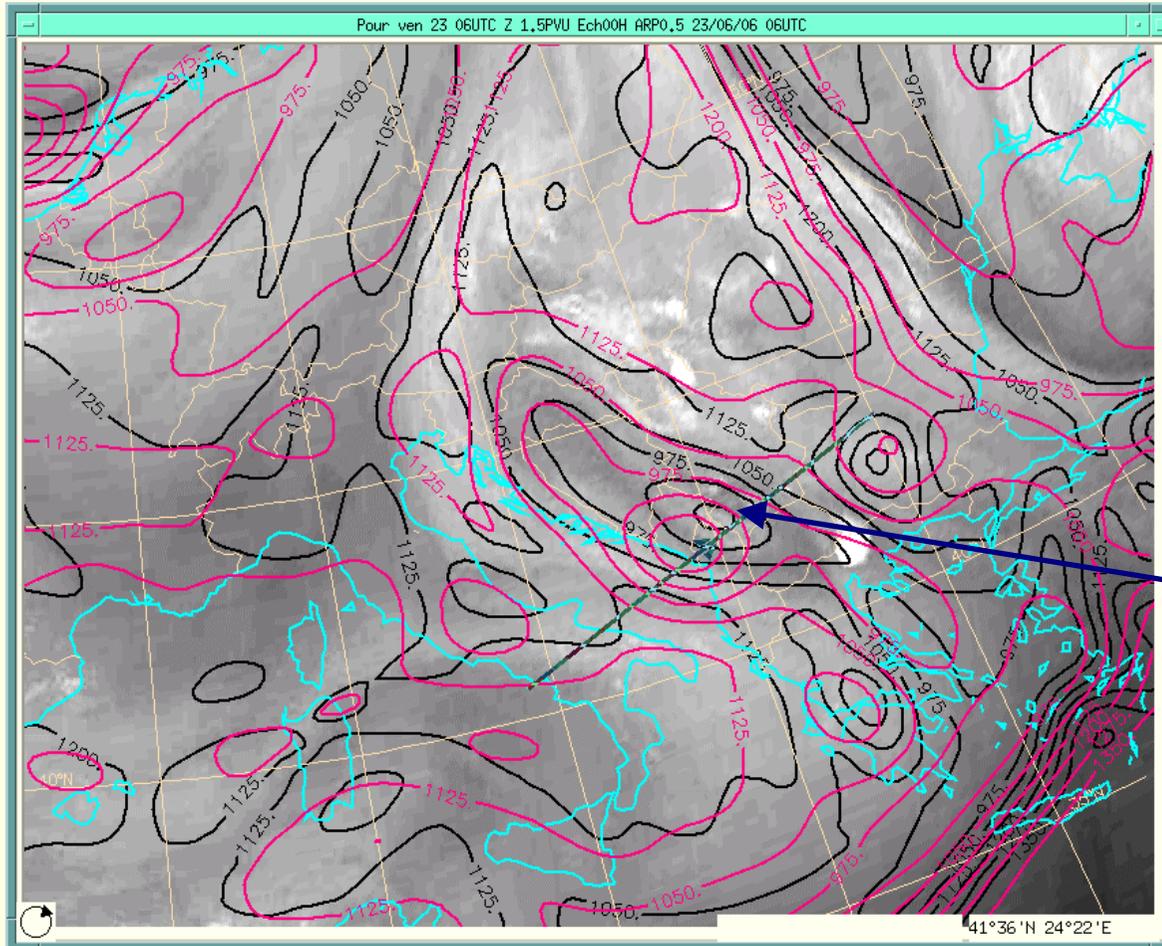

The NWP 30 h forecast underestimated the interaction between the PV anomaly and the low-level warm anomaly ( $\theta_w$  maximum) showing the leading edge of the maximum folding (in 1.5 PVU thick contour) located about 200 km to the southwest of its actual position seen in the analysis and in the WV image.

The NWP model analysis shows that the low- and the upper-level thermodynamic features are in phase on 23 June that is an important condition favourable for convective development.

6.2  $\mu\text{m}$  WV 06 UTC 1.5 PVU heights

23 June 2006

Flash floods in Sofia, Bulgaria

30 h forecast (red)  
Analysis (black)

*Wrong NWP PV  
forecast (ARPEGE)*

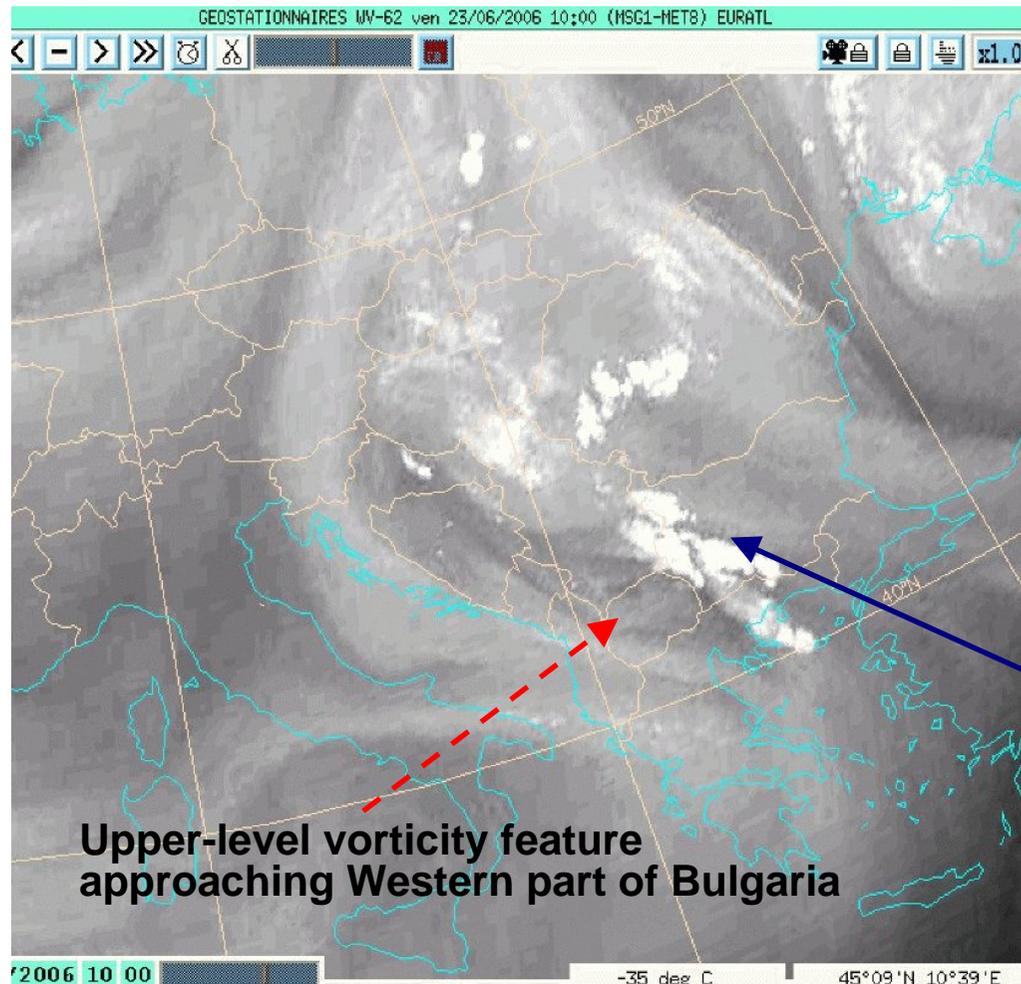

*Mismatch between the  
dynamical tropopause  
folding and the vorticity  
pattern on the WV image*

In the 30 h ARPEGE forecast, the tropopause minimum is shifted about 200 km to the southwest from the real vorticity centre seen by the satellite image. The forecast underestimates the tropopause folding, simulating a weaker tropopause height gradient (a weaker upper-level jet) than in the analysis.

6.2  $\mu\text{m}$  WV 06 UTC

23 June 2006

Flash floods in Sofia,  
Bulgaria

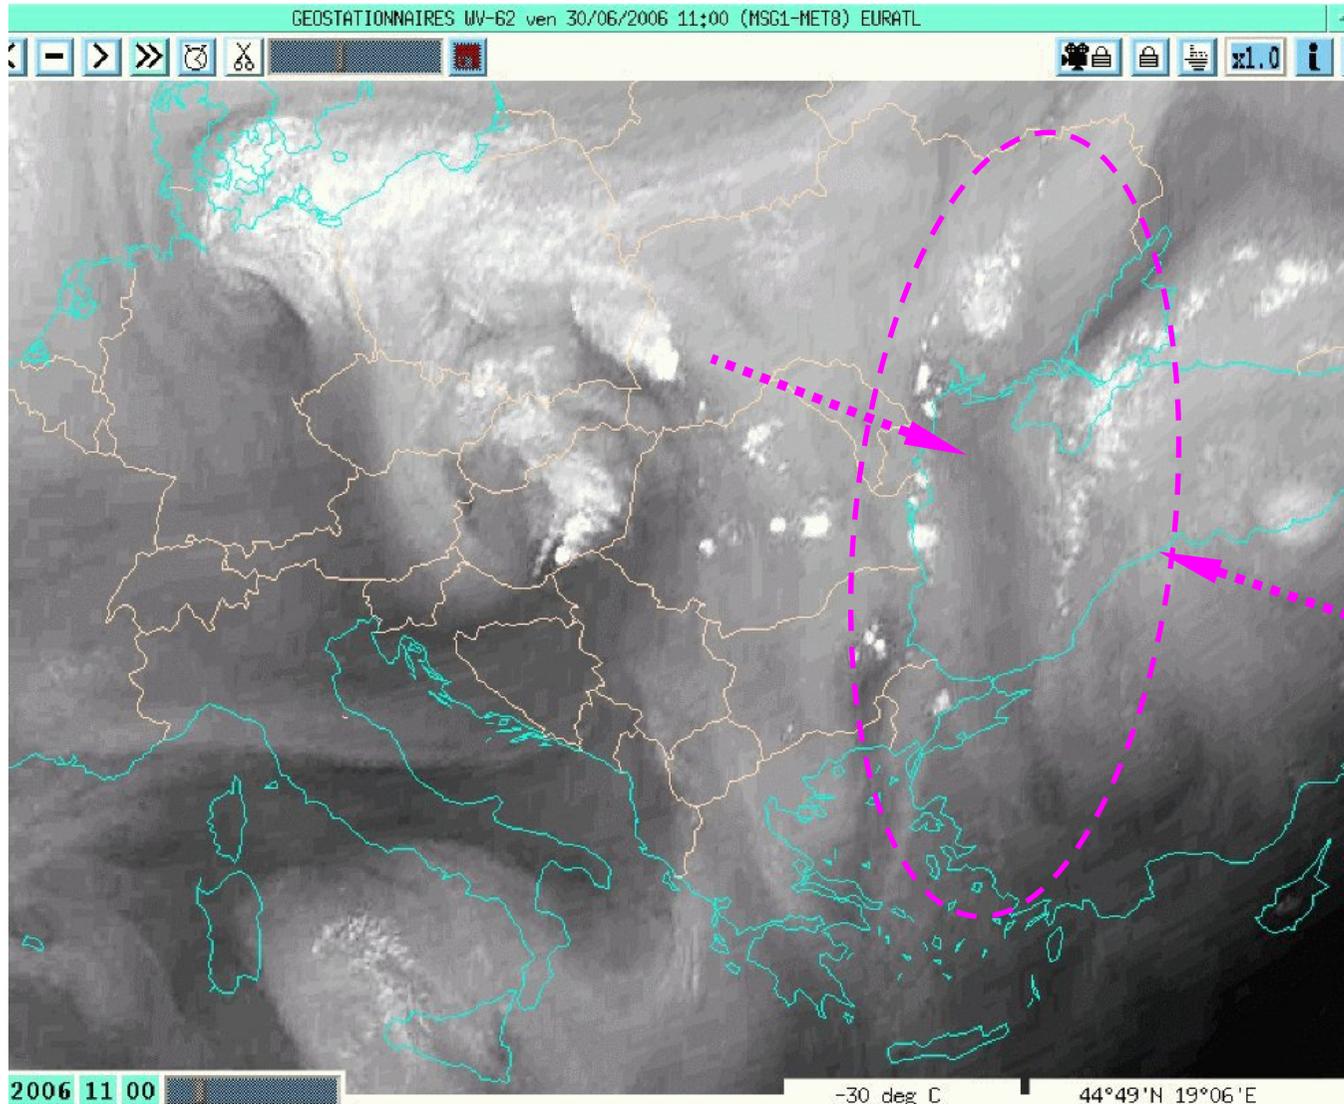

*WV imagery  
diagnosis of upper-  
level vorticity  
advection and  
forcing of  
convection*

The leading edge of the dry vorticity WV imagery feature tends to curve cyclonically being in phase with the tropopause folding, which induces strong convective development in its leading diffluent part.

## **Animation 3**

**WV 6.2**  
**500 hPa wind**

**The horizontal deformation components of the wind tend to elongate the moist system along the deformation axis (along the corresponding moisture boundaries in the WV image).**

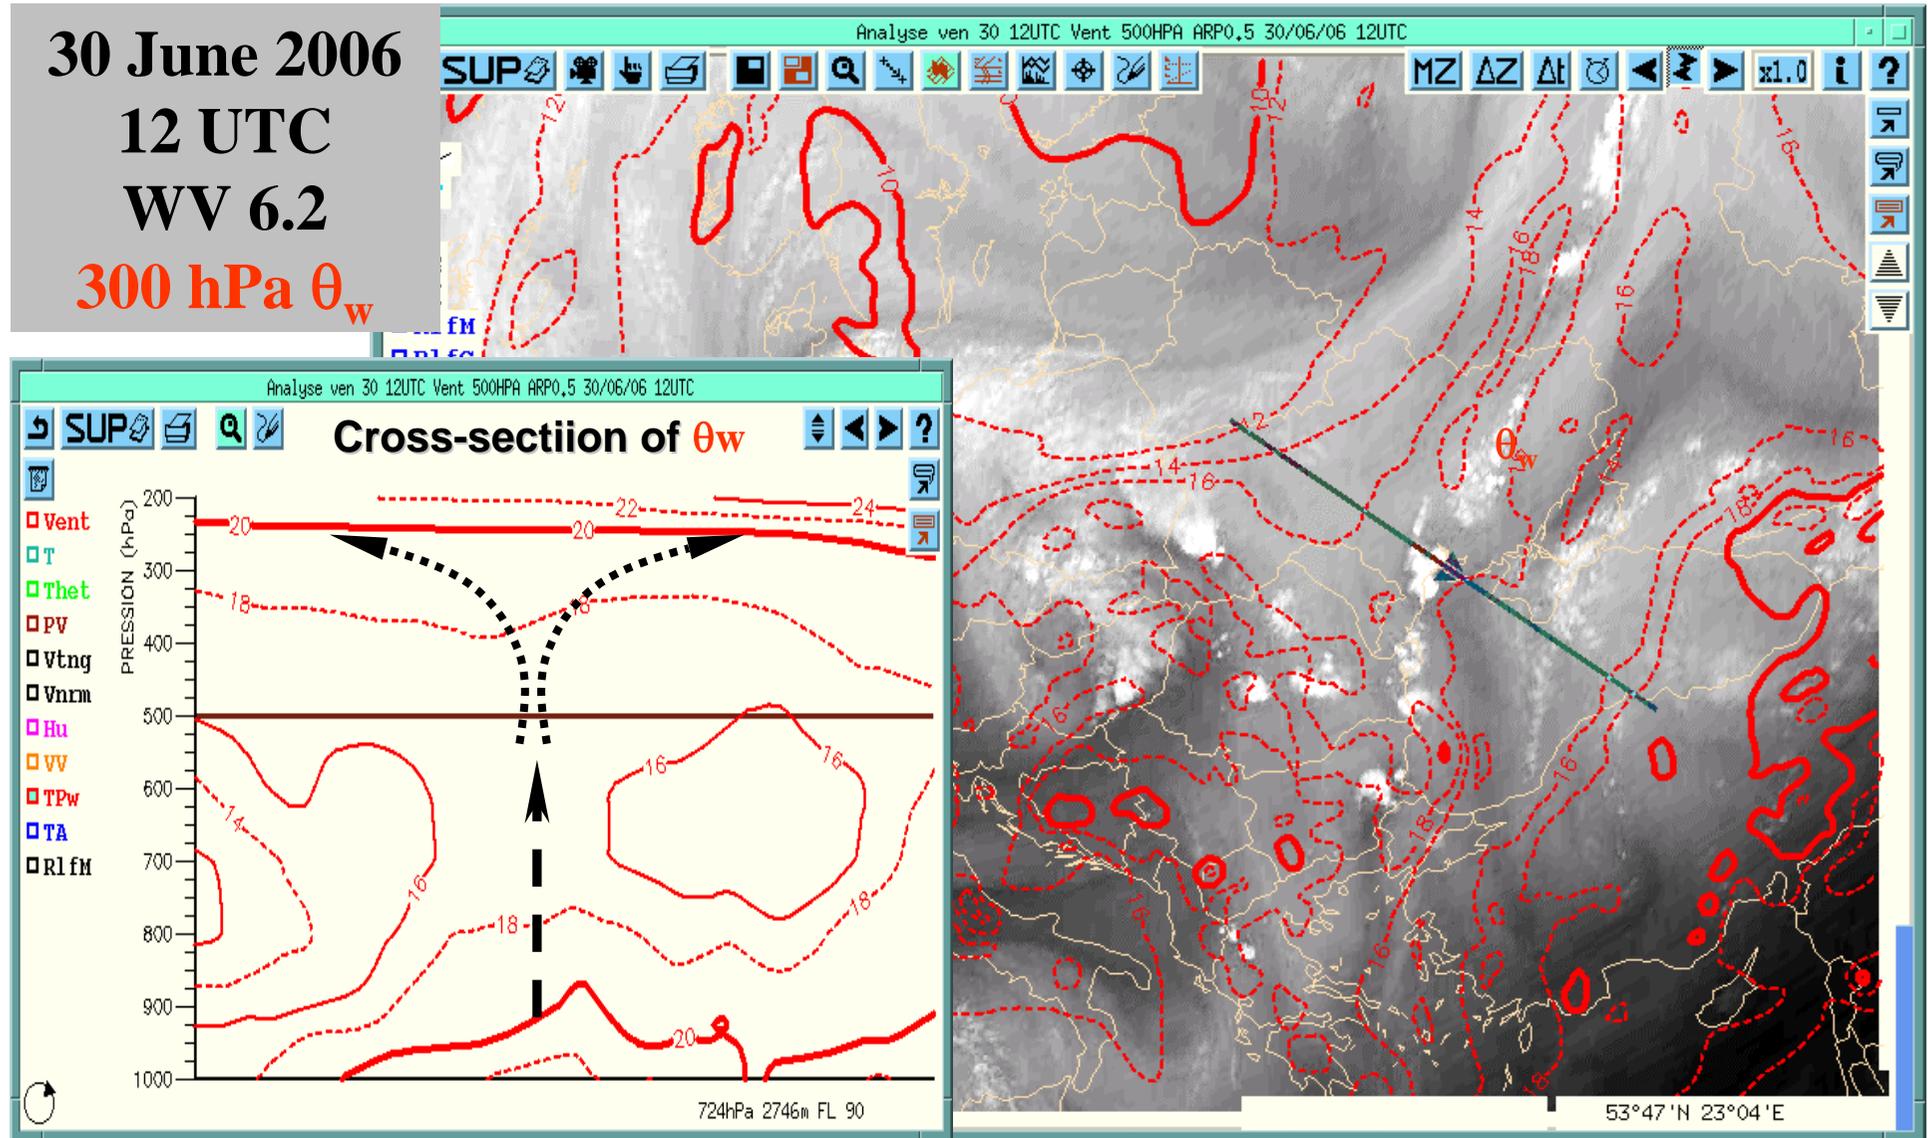

**30 June 2006  
06 UTC  
WV 6.2**

**Wet-bulb potential  
temperature  
at 300 hPa  $\theta_w$**

**In certain conditions the horizontal deformation components of the flow may tend to increase and concentrate the temperature (or potential temperature) contrasts (see Martín et al., 1997).**

30 June 2006  
12 UTC  
WV 6.2  
300 hPa  $\theta_w$

The middle troposphere at the centre of the deformation zone is unstable (weak vertical  $\theta_w$  gradient), because of the diffluent upper-level flow there. Instability from low-level increases in the presence of a warm anomaly.

## **Animation 5**

# DEEP MOIST CONVECTION

Thermodynamic context as seen in  
MSG WV channels 6.2 and 7.3  $\mu\text{m}$

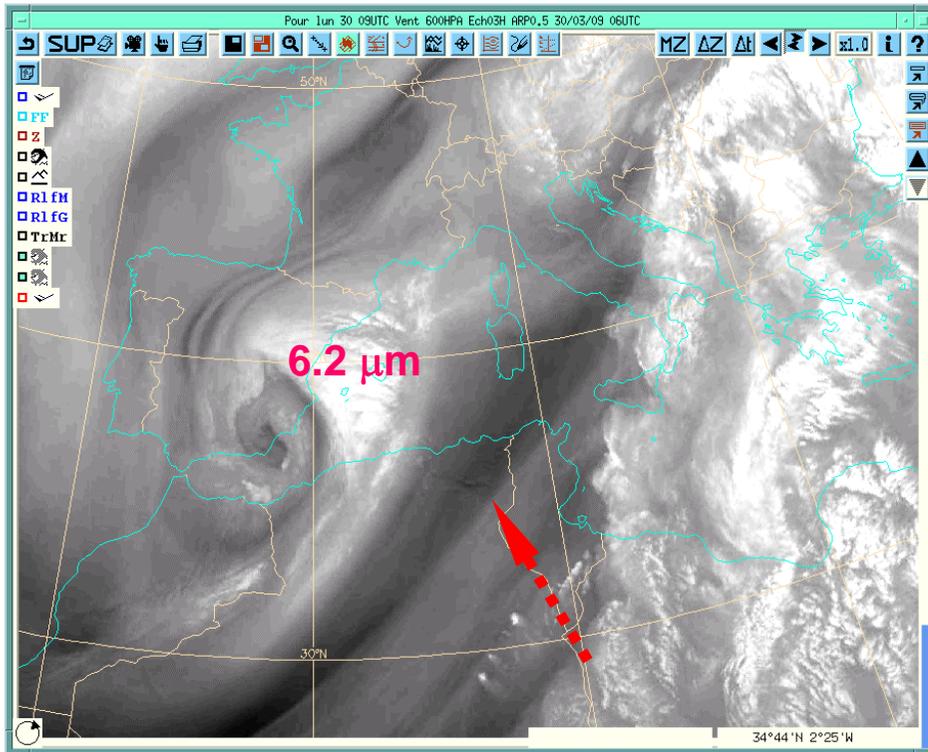

*upper-level*

*mid-level*

*low-level*

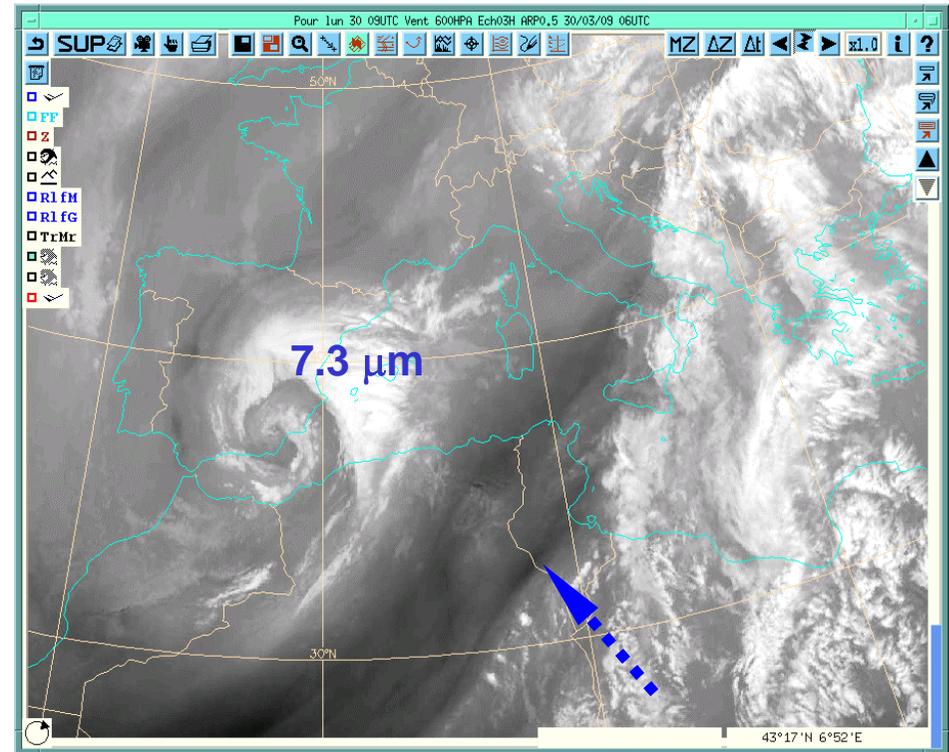

# CONVECTION at MOISTURE BOUNDARIES

30 March 2009 09 UTC

Convection often develops near moisture boundaries in WV images **channel 6.3/6.2 μm** (Roberts, 2000; Krennert, & Zwatz-Meise, 2003; Ghosh et al., 2008; Georgiev & Kozinarova, 2009)

30 March 2009 09 UTC

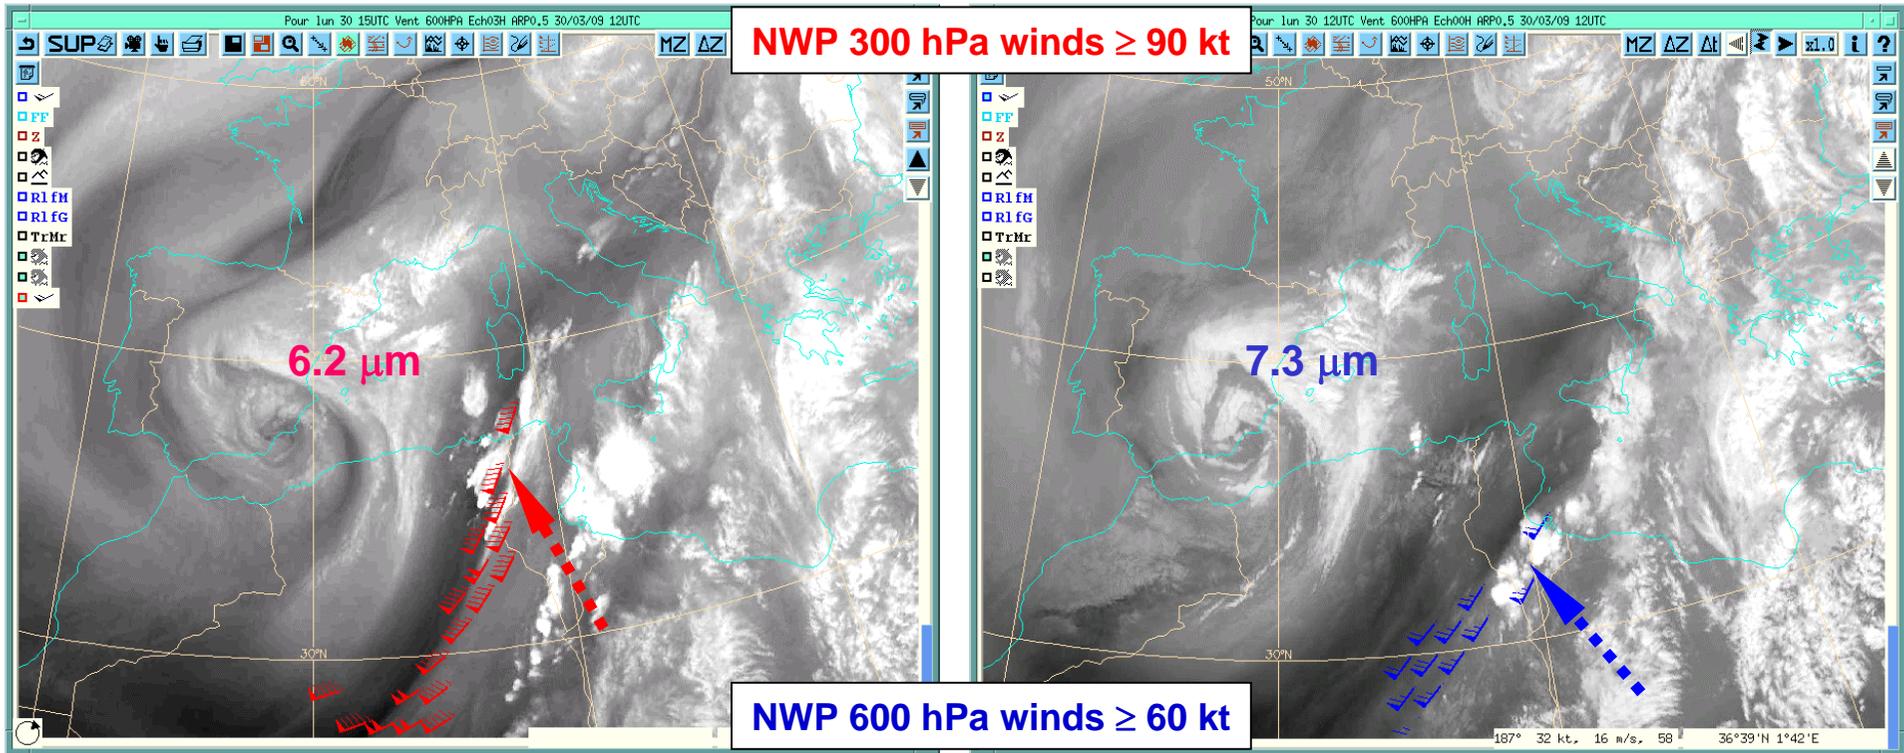

Conditions conducive for convection are present at the mid-level boundaries seen in WV images **channel 7.3 μm**, being much more distinct than on the **6.2 μm** WV images (Georgiev & Santurette, 2009).

# CONVECTION INITIATION at JETS DETECTED BY WV IMAGERY

30 March 2009 15 UTC

30 March 2009 12 UTC

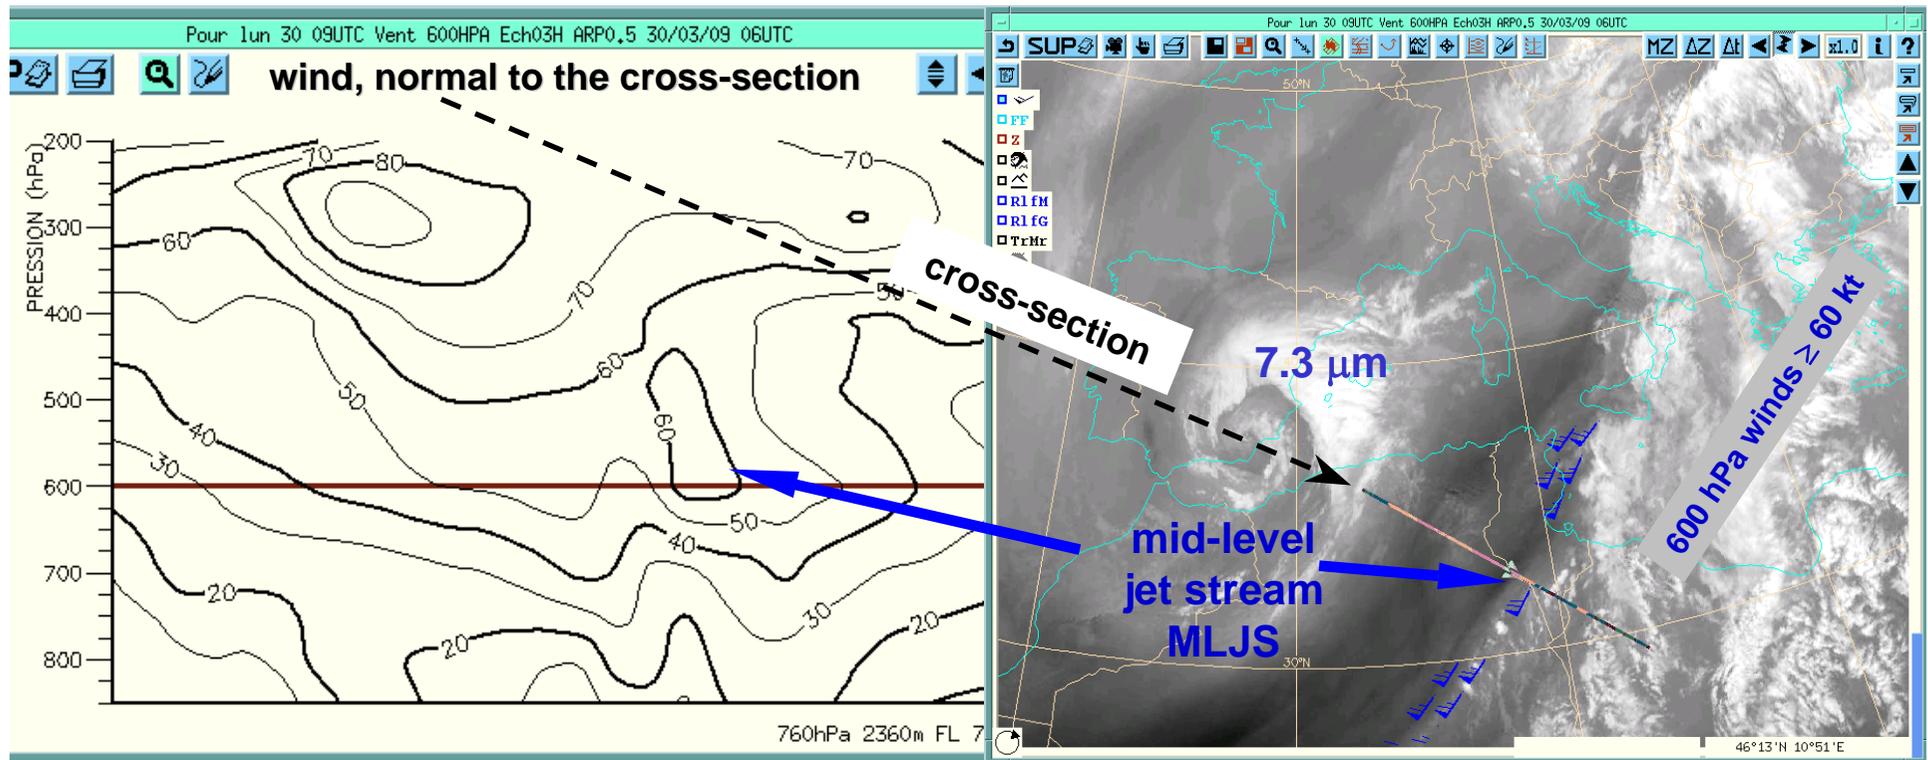

Convection initiates at boundaries of **6.2 μm images** as a result of upper-level forcing for ascent at the left exit of a jet (see Carroll 1997).

Mid-level boundaries seen in **7.3 μm images** are related to specific thermodynamic low-level convective environment (Georgiev & Santurette, 2009).

# CROSS-SECTION

A mid-level moisture boundary in 7.3  $\mu\text{m}$  images

30 March 2009 09 UTC

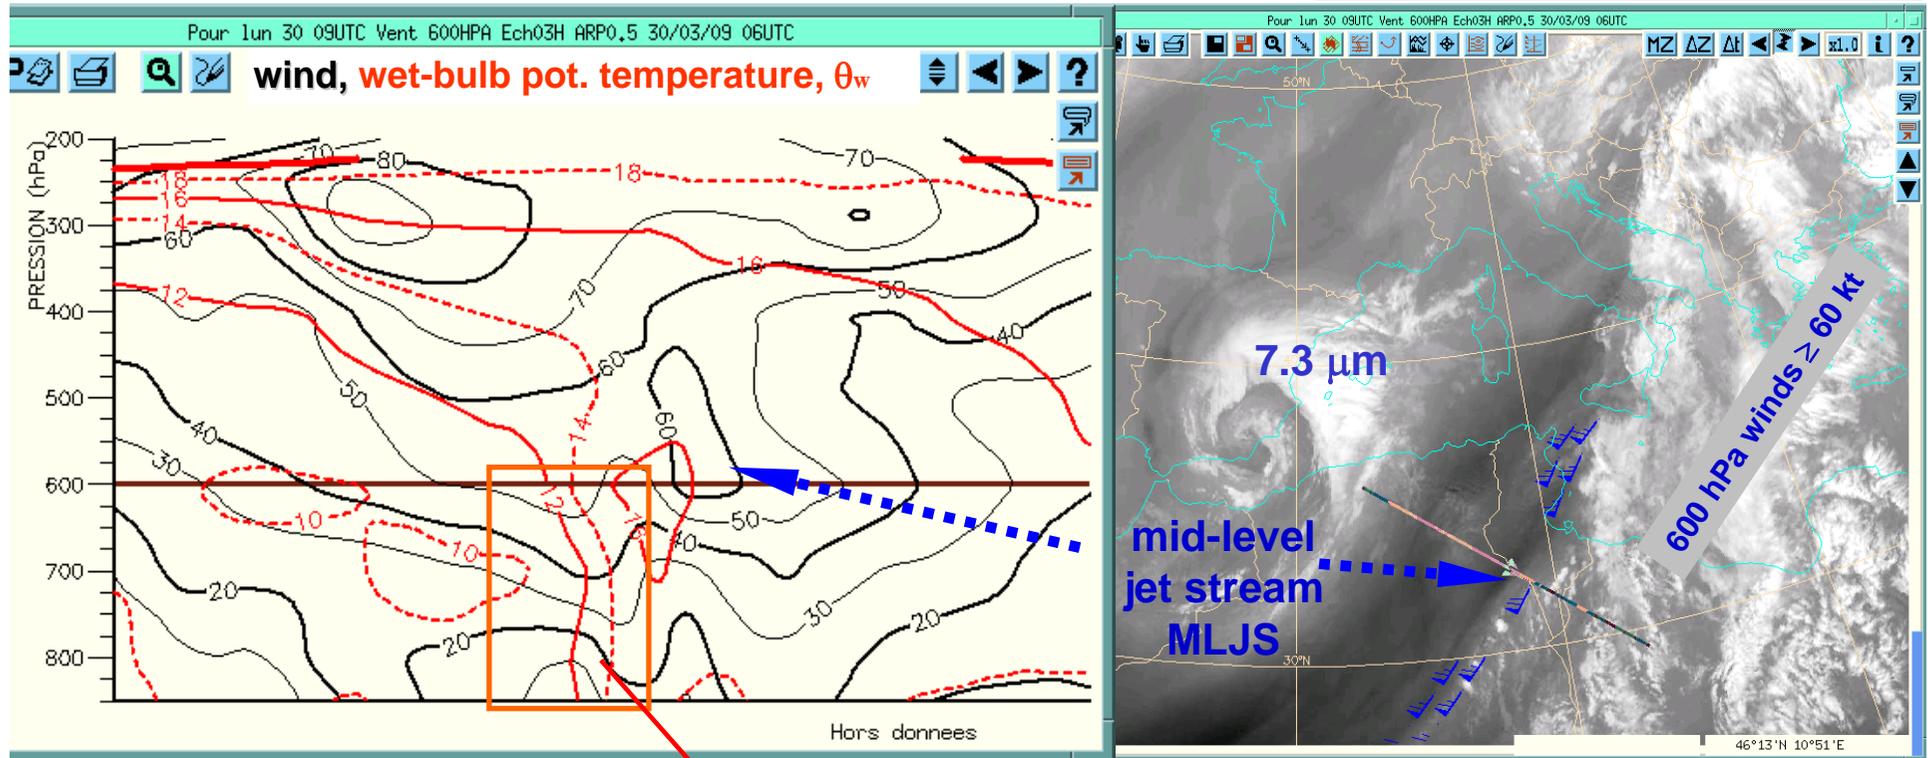

Such mid-level moisture boundaries are signatures of mid-level jet streams (MLJS), Georgiev & Santurette (2009).

A wind maximum usually appears at such moisture boundaries in 7.3  $\mu\text{m}$  images at about 600 hPa level.

# MIDDLE-LEVEL JET and BAROCLINIC ZONE

30 March 2009 09 UTC

MLJS origin : **low/mid-level baroclinic zone** (strong  $\theta_w$  gradient at 850 hPa)

Thermal wind relation :

$$\frac{g}{\theta_0} \frac{\partial \theta}{\partial x} = f \frac{\partial V_g}{\partial z}$$

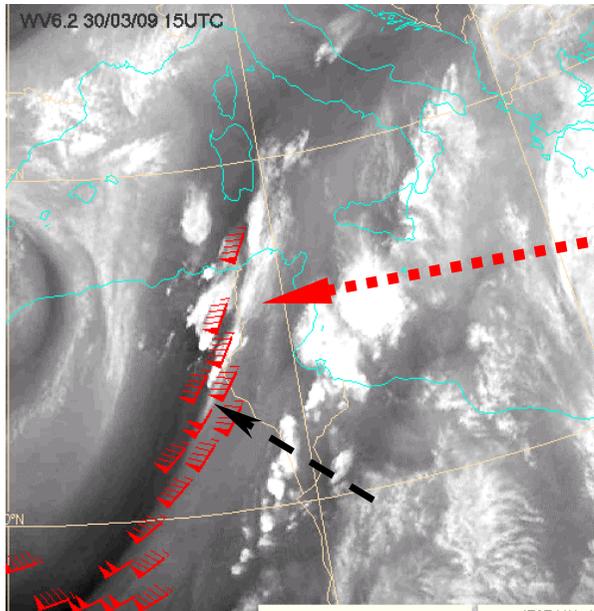

$\theta$  is pot. temperature, reference value  $\theta_0$ ,  $g$  is the acceleration of gravity,  $f$  the Coriolis parameter,  $V_g$  is the y component of the geostrophic wind.

**a strong horizontal  $\theta_w$  gradient creates a strong vertical geostrophic wind gradient**

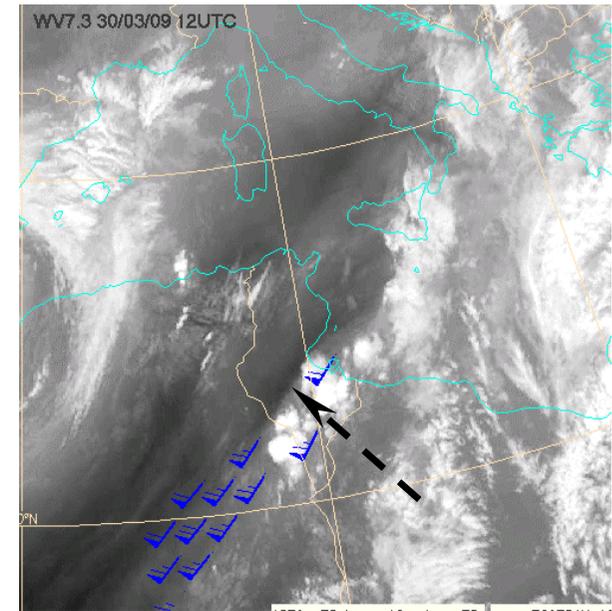

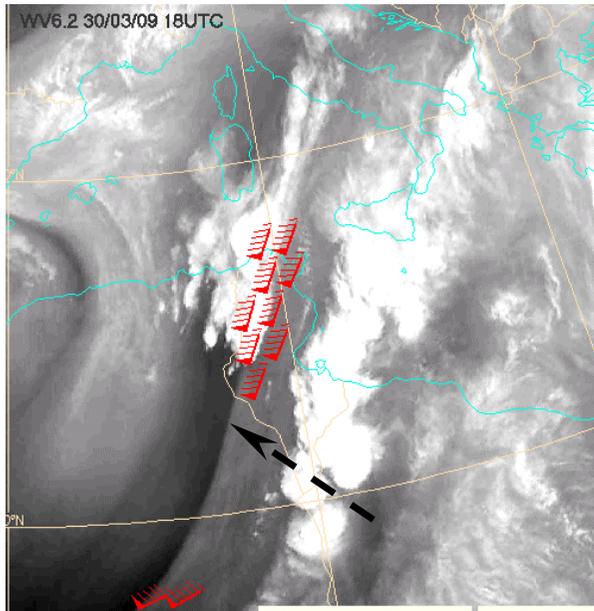

The mid-level jets, detected by **7.3  $\mu\text{m}$**  images, originate from low-level baroclinic zones (Georgiev & Santurette, 2009) and are signatures for low-level conditions, favourable for convection.

# WV IMAGERY DIAGNOSIS OF CONVECTIVE ENVIRONMENT (JET STREAM ANALYSIS PERSPECTIVE)

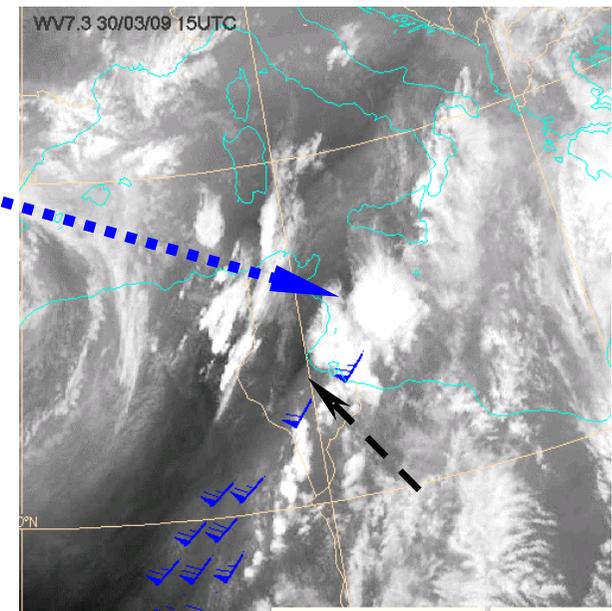

**UPPER-LEVEL  
FORCING**  
6.2  $\mu\text{m}$

Convection is most likely to develop **downstream left** of an upper-level moisture boundary

**LOW-LEVEL  
FORCING**  
7.3  $\mu\text{m}$

Convection is most likely to develop **downstream (right)** of a middle-level moisture boundary

# Conclusion remarks

## Important principles for interpreting WV images in operational forecasting environment

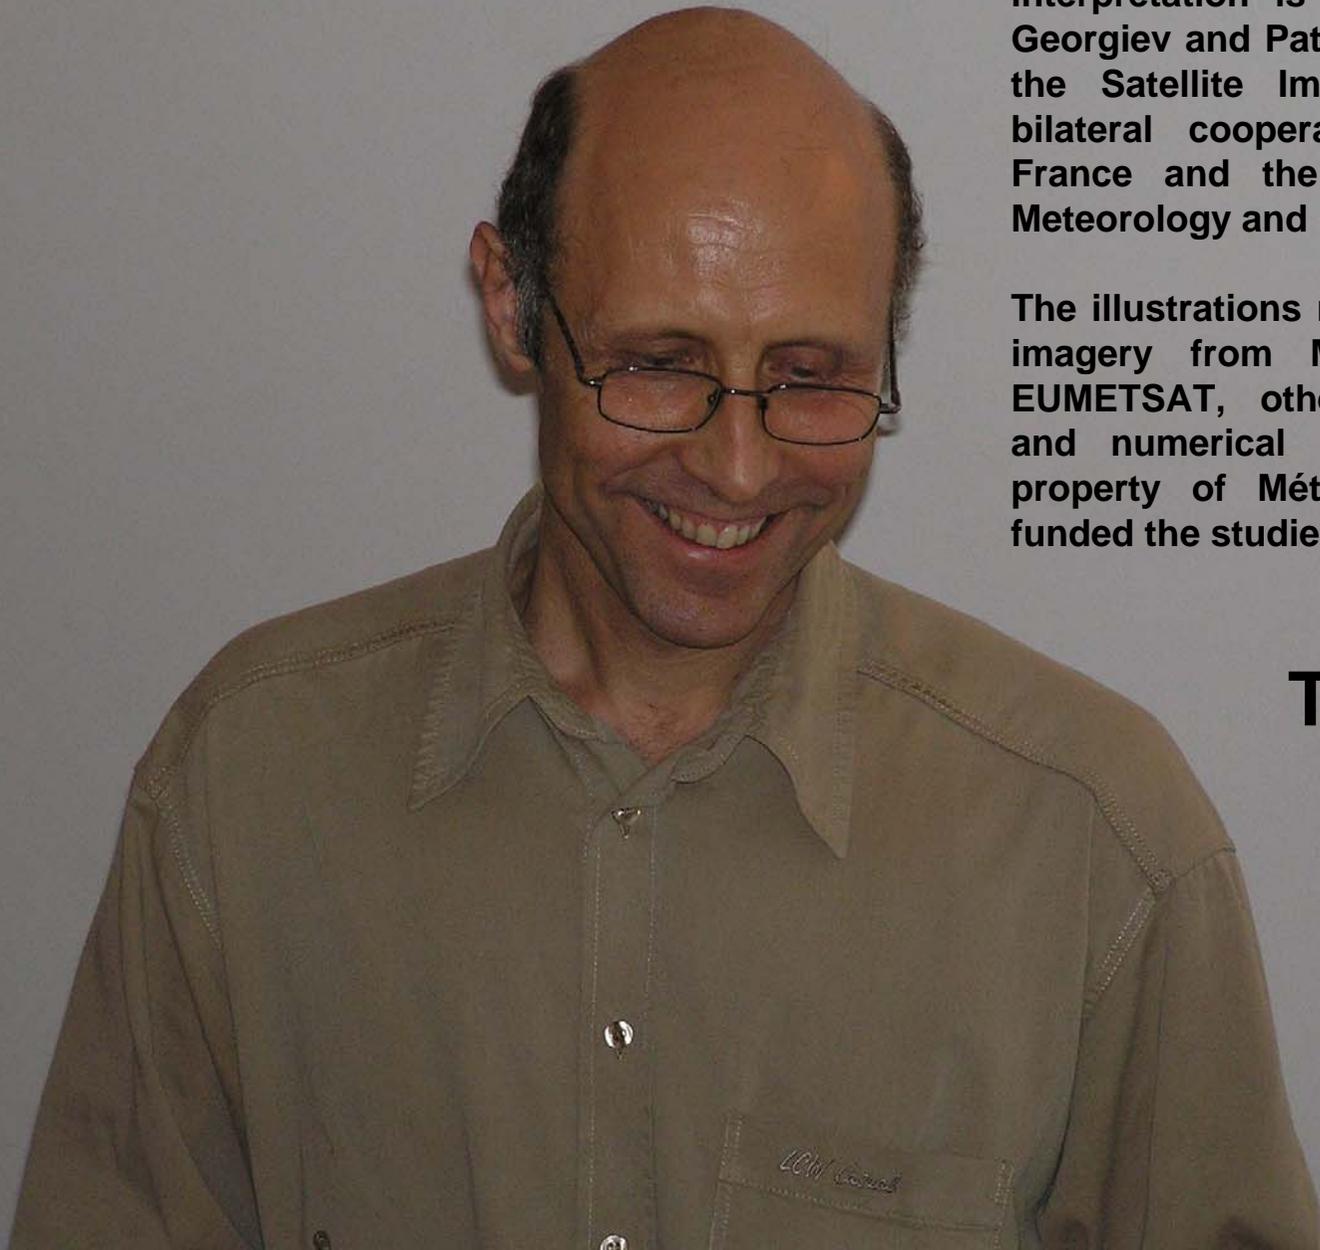

- To interpret WV images in the view of thermodynamic parameters and features, such as PV, mid/upper level wind components, wet-bulb potential temperature, etc., seen in NWP fields and vertical cross-sections.
- To estimate the potential for rapid cyclogenesis and deep moist convection through interaction of a PV anomaly (seen by WV channel 6.2  $\mu\text{m}$ ) and a low-level  $\theta_w$  anomaly (warm/moist air).
- Looking at animated WV images 6.2  $\mu\text{m}$  and 7.3  $\mu\text{m}$ , to analyse the structure and behaviour of grey-shade features that may be extrapolated to predict time changes in the related thermodynamic and moisture conditions.
- To keep a critical mind when considering the NWP model output: Priority must always be given to the data from meteorological observations and satellite imagery.

## Acknowledgments

This EUMeTrain material on WV imagery interpretation is developed by Christo Georgiev and Patrick Santurette through the Satellite Imagery Project of the bilateral cooperation between Météo-France and the National Institute of Meteorology and Hydrology of Bulgaria.

The illustrations made by using satellite imagery from Meteosat satellites of EUMETSAT, other observational data and numerical model fields are the property of Météo-France, which has funded the studies.

**Thank you!**
